PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

2400 POSSIBLE CELLULAR LOCALIZATION OF CHOLECYSTOKININ-PANCREOZYMIN. *(E.)* Kubes, L.; Jirasek, K. (Fac. Hosp. Charles Univ., Hradec Kralove, Czechoslovakia). *Experientia* 30(8):961-963, 1974.

Cellular localization of cholecystokinin-pancreozymin was investigated by introducing 15 ml of 127 mM solution (pH 7) of L-phenylalanine (a stimulator of cholecystokinin-pancreozymin secretion) into the duodenum of three anesthetized adult dogs. Samples of duodenal mucosa were taken 15 min after phenylalanine administration in two dogs and after 20 min in one dog. The samples were fixed in 5% glutaraldehyde buffered at pH 7.4, postfixed with 1% OsO_4, and embedded in Vestopal W. Ultrathin sections were stained with uranyl acetate and lead citrate and examined by electron microscope. Enterochromaffin cells were visualized throughout the whole gastrointestinal mucosa from the cardia to the large intestine. D type endocrine cells were also stimulated by the administration of phenylalanine and were seen in the gastrointestinal mucosa from the fundus, where they are sparse, to the opening of the small intestine, with maximum occurrence at the upper part of the duodenum. Their secretion granules were rounded, ranging in size from 160-400 nm. None of the other endocrine cell types were stimulated by phenylalanine administration. The hormonal product of the D type cells has not yet been identified, but the localization of these cells, with their greatest occurrence in the duodenum, corresponds to the site of cholecystokinin-pancreozymin secretion as well as to motilin localization. It is suggested that cholecystokinin-pancreozymin rather than motilin is secreted by the D cells because motilin is released under alkaline conditions whereas the D cells are stimulated under acidic conditions.

2401 DIRECT QUANTITATIVE ESTIMATION OF PANETH AND TOTAL CELL POPULATIONS IN THE JEJUNAL GLANDS OF LIEBERKUHN. *(E.)* Malinin, G. I. (Dep. Biol., Georgetown Univ., Washington, D.C.). *Am. J. Anat.* 142(2):201-204, 1975.

Direct morphometric estimation of the number of intestinal crypts/10 mm length of jejunum, the total number of cells/crypt, and the number of Paneth cells/crypt, was performed using Zenker-fixed, serially sectioned small intestines from 12 adult BALB/c mice. The intestinal segments were serially sectioned 5 μ thick and stained with hematoxylin and eosin. The sections were cut using longitudinal and transverse planes of orientation, and measurement of intestinal structures made with stage and ocular micrometers. The mean volume of a crypt cell was estimated to be in the order of 6.6×10^{-4} mm^3, while the total volume of all cells in a single crypt was 1.833×10^{-1} mm^3. The cell population/crypt was 278 cells, of which 44 were Paneth cells. It was further estimated that 265 crypts/10 mm length of jejunum contained 7.4×10^4 cells, including 1.2×10^3 Paneth cells. The volume of all crypt and Paneth cells/10 mm length of jejunum was in the order of 49 and 8 mm^3, resp. The volume of the tunica muscularis and the surface area of the crypt's lumina were estimated to be 33.5 mm^3 and 118 mm^2, resp. Most of the data reported in this study were derived from 2 basic determinations: estimates of cell population/crypt and the number of crypts/U length of the intestine. The validity of numerical values presented is determined by the nature of the assumptions made concerning cell dimensions and arrangements and cell packing effects and by the accuracy of microscopic observations. The reliability of the microscopic observations was insured by a large number of measurements and reasonably small deviation from the mean. The excellent agreement between previously published estimates of the number of crypt cells and the number estimated using this method is taken as evidence that the assumptions made were valid ones. It is concluded, therefore, that the adopted methodological approach allows valid quantitative estimates of the intestinal crypt cell populations.

2402 HISTOCHEMICAL AND ULTRASTRUCTURAL CHARACTERIZATION OF A NEW TYPE OF ENDOCRINE CELL IN THE COLONIC MUCOSA OF THE RABBIT. *(Fr.)* Pradal, G.; Lefranc, G.; Tusques, J.; L'Hermite, A. (Fac. Med., Nantes, France). *J. Microsc. (Paris)* 19(2):129-236, 1974.

Fragments of colonic mucosa were removed from pentobarbital sodium-anesthetized adult male and female rabbits, some of which had been given an injection of L-dopa (60-100 mg/kg) 1 hr previously. In contrast to serotonin-containing cells which showed yellow fluorescence with the technique of Falk and Hillarp, many small cells with a pale green fluorescence were detected, particularly at the bottom of the crypts of Lieberkuhn, in contact with the basal membrane. These green cells were argyrophilic when stained by the technique of Grimelius, but not with that of Sevier and Munger; they were not argentaffinic when stained by the technique of Fontana and Masson. The green fluorescence disappeared after treatment with sodium borohydride or HCl vapors, and the cells did not react with glyoxylic acid vapors. In rabbits given L-dopa, serotonin-containing cells retained their original properties while the pale green cells became more intensely fluorescent. This suggests that the pale green cells take up and decarboxylate L-dopa and store dopamine. Examination of colonic mucosa under the electron microscope revealed that the secretory granules in the green cells differed markedly from those in serotonin-containing cells. The granules were rounded, did not exceed 350 nm in diameter, varied in density, and were sometimes heterogeneous. Granules in the same cell could exist in different states of maturation.

2403 ORIGIN, DIFFERENTIATION AND RENEWAL OF THE FOUR MAIN EPITHELIAL CELL TYPES IN THE MOUSE SMALL INTESTINE. V. UNITARIAN THEORY OF THE

ORIGIN OF THE FOUR EPITHELIAL CELL TYPES. *(E.)* Cheng, H.; Leblond, C. P. (Dep. Anat., McGill Univ., Montreal, Canada). *Am. J. Anat.* 141(4):537-561, 1974.

Presumptive evidence that the 4 main differentiated cell types in the epithelium of the mouse small intestine (villus columnar, mucous, entero-endocrine, and Paneth cells) originate from the same precursor, the crypt-base columnar cell, was obtained in previous studies. This possibility was examined using an approach based on the observation that, after injection of 2 or 10 μCi of ^{3}H-thymidine, some crypt-base columnar cells contained a vacuole including recognizable nucleus and cytoplasm. This vacuole was interpreted as a phagosome resulting from the ingestion of a non-viable cell and was used as a marker to follow the evolution of crypt-base columnar cells. In normal male adult mice, a rare crypt-base columnar cell includes a large phagosome containing Paneth cell remnants. By 6 hr after injection of 2 μCi ^{3}H-thymidine/g body weight, a number of crypt-base columnar cells included a different type of phagosome containing labeled nucleus and granule-free cytoplasm, which is attributed to phagocytosis of a labeled crypt-base columnar cell killed by β-radiation from the incorporated ^{3}H-thymidine. By 12 hr after ^{3}H-thymidine injection, phagosomes appeared in partly differentiated mid-crypt columnar cells and oligomucous cells; by 18-24 hr, in fully differentiated columnar cells and in Paneth cells; and by 30 hr, in an entero-endocrine cell. Since phagosomes are first found in crypt-base columnar cells and only later in the 4 differentiated cell types, it is concluded that crypt-base columnar cells transform into cells of these 4 types, and therefore, behave as the stem cells of the epithelium. The findings of rare epithelial cells containing 2 different types of secretory material (either mucous globules and entero-endocrine granules or mucous globules and Paneth cell granules) confirms that the stem cells are multipotential. These findings support the unitarian theory of epithelial cell formation in the small intestine.

2404 ENZYMATIC, FUNCTIONAL AND ULTRASTRUCTURAL DEVELOPMENT OF THE EXOCRINE PANCREAS. II. THE HUMAN PANCREAS. *(E.)* Track, N. S.; Creutzfeldt, C.; Bokermann, M. (Dep. Med., Univ. Gottingen, Germany). *Comp. Biochem. Physiol.* [*A*] 51(1):95-100, 1975.

The enzymatic and ultrastructural development of human fetal, newborn and adult pancreas was studied. Low protease levels (in activity/g wet weight) were found in pancreatic tissue from fetuses 10-30 cm in crown-heel length. Values for chymotrypsin and trypsin were under 0.05 and 0.5 mU/mg protein, resp. Fetuses from 40 cm in length to term showed increased levels of these enzymes (1.0 and 6.0 mU/mg protein, resp.). In the newborn, resp. values rose to 2.0-6.0 and 25-275 mU/mg protein, and in the adult to 5.0 and 100 mU/ protein. α-Amylase was detected only in adult pancreas. Phospholipase A and lipase levels increased over the gestational period from 0.2 to 0.8 and from 1.0 to 18.0 mU/mg protein, resp. Newborn levels were 0.4-0.6 and 15.0 mU/mg protein, resp. Adult values were 2.4 and 100-130 mU/mg protein, resp. Lipase activity in the duodenum increased from 0.04 to 5.00 mU/mg protein during gestation, while in adults, values ranged from 100 to 260 mU/mg for basal secretion and 344 to 1430 mU/mg after cholecystokinin stimulation. Duodenal contents of a 23.0 cm fetus showed under immunoelectrophoresis one strongly staining, two medium staining, and three weakly staining precipitation arcs; the three stronger ones being tentatively identified as lipase, trypsin 1, and anionic chymotrypsin. No arcs were found with smaller fetuses, and a large number of strongly staining arcs were found with adult specimens. Neither enzyme activity nor any electrophoresis arcs were found in amniotic fluid. Electron microscopy showed pancreatic cells from 8.5 cm fetuses were mainly undifferentiated tubular cells with no zymogen granules and few free ribosomes. The 12.5 cm fetus showed an increase in ribosomes and the appearance of some rough endoplasmic reticulum. The 14.0 cm fetus showed active Golgi zones, increase in mitochondria, small zymogen granules, and small lysosome granules. The 15.0 fetus to the 19.0 cm fetuses showed gradual increase in cellular activity, enhanced activity of the rough endoplasmic reticulum, condensing vacuoles, and zymogen granules of varying shape and size. The 21.0 to 26.0 cm fetuses showed a greater number of pancreatic cells with increased cellular activity and zymogen granule content. The 32.0 fetus showed still more highly organized exocrine cells the zymogen granules increased in number and electron density, and ductular lumina containing electron opaque material. The adult cell contained a prominant rough endoplasmic reticulum, and Golgi apparatus, and abundant dense zymogen granules in the cell apex in a limiting membrane. It is concluded that the human fetus can release pancreatic enzymes to digest swallowed amniotic fluid, and the development of this ability correlates with ultrastructural events in the exocrine cells.

2405 INTRACISTERNAL INCLUSION BODIES INDUCED IN ANIMALS: THEIR TRANSFORMATION AND SIGNIFICANCE. *(E.)* Watari, N. (Nagoya City Univ. Med. Sch., Japan). *J. Electron Microsc. (Tokyo)* 23 (4):255-268, 1974.

Electron micrographic studies in the pancreas of a number of species under normal and stressful conditions is reported. Two groups of bats (*Myotis lucifugus*) were kept at temperatures of 10 C and 20 C, resp., for four weeks, and the second group was fed after arousal. All were sacrificed within 4-24 hr. Wistar rats were kept at 1 C for 40 days and sacrificed. Dogs were given 200 mg/kg alloxan i.v. and sacrificed after 1-24 hr. Mice (ddy strain) were continually given 1 ppm γ-benzene hexachloride in drinking water for 1-12 months, or were injected with 200-400 IU vitamin A semiweekly for 1-18 months, or with 100 mg vitamin E daily for 2 weeks. Carp (*Cyprinus carpio*) were injected with 19 g/kg of 50% glucose i.p. and sacrificed after 1-2 hr. A cat with cystic fibrosis was sacrificed. For controls, intact animals of the above species, plus guinea pig and yellow-tail fish (*Seriola quinqueradiata*) were sacrificed. Pancreatic tissues of the animals were fixed in either 2.5% glutaraldehyde and 2% osmic acid, or in 1% osmic acid. Liver samples were also fixed in 1% osmic acid. Electron microscopy showed the population of cells containing the intracisternal inclusion bodies was low except in the exocrine pancreas of the rat after cold treatment, and of the normal guinea pig. The inclusion bodies were classified into six morphological types. A round granular type, electron dense, was found in a single form in guinea pig pancreatic acinar cells, and in a multiple form in post-hibernation bat pancreas, and mouse pancreas exocrine cells after vitamin A treatment. A multivesicular form with low electron density spherical bodies containing lower electron density vesicles was found in vitamin A-induced mouse hepatomas, and rarely in mouse hepatocytes exposed to γ-benzene hexachloride. A filamentous type resembling collagenous fibers was also found in the mouse hepatomas. A crystalline type, electron dense and rectangular, was observed in previous experiments, in rat pancreatic acinar cells, after chlorophenylalanine treatment. An irregular particular type with low electron density was found in hepatic cells of mice given vitamin E. A collodial type, very electron dense, consisted of three subtypes: a monocolloidal subtype (large spherical granules) found in islet B cells of intact carp; a multiconfigurational subtype found in the ganglion-like cells of carp pancreas 2 hr after glucose injection; and an arbor-like configuration subtype found in the anterior pituitary of marine teleosts kept in fresh water. It is suggested that these various inclusion bodies represent secretory substances retained in the endoplasmic reticulum when passage to the Golgi apparatus is inhibited.

2406 STUDIES ON THE DEPLETION AND ACCUMULATION OF MICROVILLI AND CHANGES IN THE TUBULOVESICULAR COMPARTMENT OF MOUSE PARIETAL CELLS IN RELATION TO GASTRIC ACID SECRETION. *(E.)* Ito, S.; Schofield, G. C. (Harvard Med. Sch., Boston, Mass.). *J. Cell Biol.* 63(2):364-382, 1974.

Parietal cell structure and function was studied by examining the cytological effects of insulin injection and reserpine administration in adult male Swiss-Webster mice. Differences in the range of forms among parietal cells of fasting *versus* fed mice were not striking, but cells with numerous tubules and vesicles were more common after fasting. Parietal cells showed a homogeneous appearance within 40 min after insulin (0.1-5 U/kg, i.p.) or pentagastrin (125 μg/kg) injections. These effects persisted for 2 hr. Cytoplasmic tubules were often completely depleted while there was a concomitant increase in both number and size of microvilli. Measurements of acid secretion in control animals and in animals treated with acid secretagogues indicated H^+ secretion contemporaneous with depletion of the cytoplasmic tubulovesicular membranes and with increase of the microvilli. Two sets of dose-dependent changes occurred in reserpine-treated fasting mice. In mice given low doses of reserpine (0.1-0.5 mg/kg, i.p.), parietal cells were similar in appearance to those in animals stimulated with insulin or pentagastrin. These changes occurred as early as 30 min after injection and persisted 5 hr. After administration of high doses of reserpine (5 mg/kg) changes opposite to those induced by insulin, pentagastrin, or low doses of reserpine were seen. Parietal cells accumulated cytoplasmic tubules and vesicles and had reduced numbers of microvilli 4 hr after injection which persisted for 24 hr. Sterological methods quantitated 10 different parietal cell components. Tracer studies with lanthanum revealed no continuity between tubules and the plasma membrane. There were, however, regions of close apposition between the tubulovesicular membranes and the cell membrane of the canaliculus, and instances where cytoplasmic tubules extended from the cell into the core of enlarged microvilli. These results support earlier findings that hydrogen ion release is associated with a reduction in the tubulovesicular membrane content of parietal cells and an increase in the area occupied by intracellular canaliculi and their microvilli. The results of this study suggest that a role for cytoplasmic tubules as reservoirs for the storage of a secretory product is unlikely. It is suggested that the dissolution of tubulovesicular membrane may be involved in some aspects of the reconstitution of new microvillous membrane. It seems probable that during secretion there is redistribution rather than complete loss of this membrane from the cells so that, during reconstitution of the tubules, some part of the membrane or membrane constituents is available for recycling.

2407 LIPOPROTEIN PARTICLES IN THE JEJUNAL MUCOSA OF FETAL RATS. *(E.)* Mak, K. M.; Trier, J. S. (Harvard Med. Sch., Boston, Mass.). *Dev. Biol.* 43(1):204-211, 1975.

Lipoprotein production was studied in the fetal rat small intestine. Forty-five fetuses from 15 timed pregnant Sprague-Dawley rats were obtained by laparotomy at gestational ages of 18-22 days. Segments of proximal jejunum were fixed in osmium tetroxide, stained with uranyl nitrate and saturated lead acetate, and examined by electron microscopy. Eighteen day fetal specimens showed no morphological evidence of lipoprotein, but 19 and 20 day specimens showed particles 250-500 Å in diameter in absorptive cells of the apical portions of developing villi. These corresponded in size, electron density, and intracellular location with adult very low density lipoprotein particles. The number of these particles was greatly increased in the 21 and 22 day fetuses, the diameters were from 500-800 Å, and were found mainly in the endoplasmic reticulum (in contrast to the particles from the 19-20 day specimens which were found mainly in the Golgi apparatus). It is concluded that fetal rat small intestine epithelium is capable of synthesizing lipoprotein particles.

2408 ELECTRONMICROSCOPIC STUDIES ON THE DIFFERENTIATION AND THE ONTOGENESIS OF GASTRIC EPITHELIUM CELLS OF RAT EMBRYO. *(E.)* Matsumoto, T. (no affil.). *Arch. Jpn. Chir.* 42(1):293-314, 1973.

The kinetics of growth and differentiation of rat gastroepithelial cells was studied by electron microscopy. Stomachs of embryonic and fetal rats *(Rattus norvegicus albus)* were excised and fixed in glutaraldehyde or osmium tetroxide, and stained in uranyl acetate and lead oxide. Development fell into 3 stages. The first, the plane stage, lasted from about 7-14 days of fetal age and was characterized by the first appearance of columnar cells, surface mucosal cells and cells possessing small granules among the undifferentiated cells. The undifferentiated cells at this point were distributed over the plane basal membrane in a monolayer. The gastric pit stage followed, lasting from 17-24 days of age. Urn-like arrangements of undifferentiated cells appeared and began to develop into gastric pits, containing mucous cells. Parietal cells and basal clear cells also began to appear. Finally, the stage of gastric chief gland formation lasted from birth to 28 days. During this time the chief cells and basal granular cells made their appearance. By 31 days after birth the gastric glands were similar to those of the adult.

2409 ENTEROCHROMAFFIN CELLS IN THE GUINEA PIG DIGESTIVE TUBE IN RELATION TO AGING. *(E.)* Gandalovicova, D. (Inst. Pharm. Biochem., Prague, Czechoslovakia). *Folia Morphol. (Praha)* 22(1):102-108, 1974.

The incidence of enterochromaffin cells in the stomach and small and large intestine was studied by the Masson-Hamperl argentaffin reaction and the diazo reaction in guinea pigs belonging to 4 age groups: 2 days, 60 days, 6 months, and 2 1/2 yr. The number of enterochromaffin cells was expressed as the count/1000 epithelial cells of the intestinal villi and the gastric and intestinal glands. The following results are presented in order of increasing age as defined by the four groups above. For the cardia, as determined by the argentaffin reaction, the incidence of enterochromaffin cells for the four age groups was 4.0, 11.7, 14.1, and 17.8. Also for the cardia, but determined by the diazo reaction, the incidence of enterochromaffin cells for the four age groups was 2.0, 7.8, 11.1, and 13.5. For the fundus, determined by the argentaffin reaction, the values were 2.31, 7.8, 8.9, and 11.1; determined by the diazo reaction, 0, 3.1, 2.5, and 2.8. For the pylorus determined by the argentaffin reaction, the values were 1.1, 2.9, 3.0, and 2.0; determined by the diazo reaction, 0, 0, 0, and 0. For the duodenum as determined by the argentaffin reaction, the values were 32.3, 35.9, 35.2, and 48.0; determined by the diazo reaction, 21.5, 24.0, 25.2, and 28.8. For the jejunum, as determined by the argentaffin reaction, the values were 17.5, 20.0, 21.7, and 27.6; determined by the diazo reaction, 7.8, 11.7, 12.0, and 15.0. For the ileum, determined by the argentaffin reaction, the values were 13.9, 16.1, 19.9, and 27.2; determined by the diazo reaction, 1.0, 3.5, 4.5, and 5.1. For the colon, determined by the argentaffin reaction, the values were 26.6, 17.7, 13.2, and 12.7; determined by the diazo reaction, 10.0, 3.3, 2.0, and 0.8. These results indicate that in practically all parts of the digestive tract, the enterochromaffin cell count rose from the group of guinea pigs aged 2 days to the group aged 2 1/2 yr, with the colon as an exception. The number of enterochromaffin cells visualized by the Masson-Hamperl silver impregnation method was larger than the number shown by the diazo reaction. Finally, it was concluded that the distribution of the enterochromaffin cells in the individual parts of the guinea pig digestive tract was, in general, similar in all age groups.

2410 TOPOGRAPHIC RELATIONS OF LYMPHATIC ENDOTHELIAL CELLS IN THE INITIAL LYMPHATIC OF THE INTESTINAL VILLUS. *(E.)* Collan, Y.; Kalima, T. V. (2nd Dep. Pathol., Univ. Helsinki, Finland). *Lymphology* 7(4):175-184, 1974.

Endothelial joint areas in the walls of initial lymphatics were studied with respect to morphology and interrelationships with each other. Specimens were taken from dilated and non-dilated lymphatics of 17 Sprague-Dawley rats and prepared for electron micrography. Dilation or non-dilation was produced by ligating the lymphatics at the base of the mesentery in 2 rats; venous stasis for 1, 10, or 20 min in 6 rats; 1 mg of papaverin administered i.v. in 2 rats; and the mesenteric veins opened for 5 min in 2 rats. There were 5 controls. Five serial sections were cut from 2 specimens with dilated lymphatics and open valves, 3 were from animals with venous stasis for 1 min, and 2 were from papaverin-treated animals. Each serial section had a light microscope section cut before and after the serial section. All sections were cut perpendicular to the intestinal villi at the central portion. Most joint areas contained 1-6 junctions which appeared to be zonulae adherentes. Joint areas were classified as simple (valve-like with 2 overlapping leaves) or complicated (containing more than 2 layers but no more than 2 cells, and having 1 or more cellular junctions). Simple joints were more common in dilated than compressed lymphatics. Serial sections showed that in both simple and complicated joints, closed areas sometimes changed to open ones, and that both joint types were mutually convertible to one another. It is concluded that variation of appearance of joint areas is due to both the natural structure of the lymphatic and its functional status.

2411 THE DEVELOPING HUMAN FETAL PANCREAS: AN ULTRASTRUCTURAL AND HISTOCHEMICAL STUDY WITH SPECIAL REFERENCE TO EXOCRINE CELLS. *(E.)* Laitio, M.; Lev, R.; Orlic, D. (Dep. Pathol., Univ. Turku, Finland). *J. Anat.* 117(3):619-634, 1974.

Zymogen granule production in human exocrine pancreas was studied during the middle trimester of fetal life, and the observations compared with corresponding adult pancreatic acinar organelles. For electron microscopy, fragments of pancreas were obtained from seven 9-20 week fetuses, fixed in glutaraldehyde, postfixed in osmium tetroxide and stained with toluidine blue, lead citrate and uranyl acetate, or left unstained. For histoenzymatic studies, tissues from three 15-20 week fetuses were cryostat sectioned at 6-8 µm. Enzymes studied included: alkaline phosphatase, acid phosphatase, leucine aminopeptidase, non-specific esterase, and thiamine pyrophosphatase. In addition, paraffin sections of pancreas from twelve 12-35 week fetuses were studied for general morphology, protein, and neutral glycoproteins to determine the time of appearance of exocrine acini and zymogen granules. Electron microscopy revealed no acinar cells in the 9 week pancreas, but a few appeared at 12 weeks containing small zymogen-like granules. During the 12-19 week period, the number of small zymogen granules gradually increased but were restricted to the area between the Golgi cisternae and the apical membrane. The small zymogen-like granules gradually decreased in number at the same time. Histoenzymatic studies demonstrated that pancreatic duct epithelial surfaces were negative for alkaline phosphatase at all fetal ages, while pancreatic stroma endothelium was positive. Non-specific esterase and leucine aminopeptidase were found in particulate deposits in acinar cytoplasm of all age groups. Thiamine pyrophosphatase was found in punctate deposits in acinar cell supranuclear cytoplasm, and did not vary with age. Light microscopy showed exocrine acini at 14-16 weeks. These showed a progressive increase in number of zymogen granules and cytoplasmic basophilia with toluidine blue. Paraffin sections showed primitive exocrine acini at the end of the third fetal month, but significant numbers of granules were not found until the fifth month. It is concluded that acinar cells appear by 12 weeks and mature over the next two months.

2412 COMPLETE IDENTIFICATION OF ENDOCRINE CELLS IN THE GASTROINTESTINAL TRACT USING SEMI-THIN-THIN SECTIONS TO IDENTIFY MOTILIN CELLS IN HUMAN AND ANIMAL INTESTINE. *(E.)* Polak, J. M.; Pearse, A. G. E.; Heath, C. M. (R. Postgrad. Med. Sch., London, England). *Gut* 16(3):225-229, 1975.

The serial semithin-thin section technique was used to demonstrate association of gastrin with G cells for complete identification of motilin cells in the small intestine. Small fragments of duodenal and jejunal mucosa from man, pig and dog were fixed and sectioned. Successive (serial) sections were subjected to immunofluorescence, silver impregnation and electron microscopy, or silver impregnation and light microscopy. Of 128 blocks, 28 were immunofluorescent for motilin, and only 12 could be used for correlation between light and electron microscopy due to technical difficulties. However, immunofluorescent motilin cells were shown to be identified with electron micrograph cells containing the electron dense nonspherical granules generally associated with enterochromaffin cells. Light microscopy further confirmed this by showing the storage granules of the motilin cells to be argentaffin. It is concluded that the enterochromaffin cell is the source of motilin, and that this technique offers the best possibility of correlation between ultrastructural morphology and immunocytochemistry.

2413 IMMUNOCYTOCHEMICAL LOCALIZATION OF SUBSTANCE P IN MAMMALIAN INTESTINE. *(E.)* Pearse, A. G. E.; Polak, J. M. (R. Postgrad. Med. Sch., London, England). *Histochemistry* 41(4):373-375, 1975.

Fresh samples of small and large intestine from man, dog, pig, and baboon were freeze dried and fixed in a number of non-aldehyde fixatives. The tissues were then subjected to indirect immunofluorescence with antibodies to synthetic substance P, using as controls normal rabbit serum as the first layer, second layer alone, or first layer antiserum with synthetic substance P. The controls were all negative and immunoreactive substance P was demonstrated in the cell bodies and processes in the plexuses of Auerbach and Meissner. In addition, immunofluorescence was found in the cytoplasm of numerous basigranular endocrine cells in the intestinal mucosa of all 4 species, tentatively identified as enterochromaffin cells. It is concluded that the enterochromaffin cell is probably of neuro-ectodermal origin.

2414 THE NORMAL HUMAN ESOPHAGEAL MUCOSA: A HISTOLOGICAL REAPPRAISAL. *(E.)* Weinstein, W. M.; Bogoch, E. R.; Bowes, K. L. (Dep. Med., Univ. Alberta, Edmonton, Canada). *Gastroenterology* 68(1):40-44, 1975.

In 19 asymptomatic subjects (18-47 yr old; 12 women and 6 men), a total of 95 mucosal suction biopsies were taken from multiple sites in the distal 10 cm of esophagus and examined for evidence of basal cell hyperplasia and elongated dermal papillae, features considered to be histological consequences of gastroesophageal reflux. Five of the 19 subjects had either a positive acid infusion test or an abnormal manometric study. In these 5 subjects, 7 of 25 biopsies (28%) were abnormal, whereas 29 of 70 (41%) biopsies were abnormal in the 14 subjects who had both a normal acid infusion test and manometry study. Features of basal cell hyperplasia and elongated dermal papillae were seen in 57% of the biopsies in the distal 2.5 cm of the esophagus and 19% of the biopsies above 2.5 cm. It is concluded that these histological criteria are unlikely to be of significant diagnostic value in a clinical setting when 1 or 2 biopsies are taken, even above the most distal 2.5 cm of esophagus.

2415 ARGENTAFFIN GRANULES IN ENDOCRINE CELLS IN HUMAN DUODENAL MUCOSA. *(E.)* Tateishi, R. (Cent. Adult Dis., Osaka, Japan). *Arch. Pathol.* 99 (4):220-224, 1975.

Ultracytochemical studies of the endocrine cells of human duodenal mucosa were made to correlate individual cell type with serotonin production. Tissues were obtained from 2 patients undergoing surgery for gastric carcinoma, fixed in glutaraldehyde, and subjected either to routine electron microscopy, or to electron microscopy after silver impregnation by either the argyrophil or argentaffin reactions. Normal electron microscopy divided the endocrine cells into 3 types according to the size and shape of the secretion granules. The first type had numerous granules less than 200 mμ in diameter with round cores that were either homogeneous and electron dense, or finely granular. The second type had fewer granules; these varied from 70-400 mμ in diameter and were uniformly round. The third type had generally a lower number of granules than the first 2, and measured from 100-500 mμ in the shortest diameter. The cores were electron dense, and either round, oval, tear-drop, rod-like, or concave. The silver grains of both argyrophil and argentaffin reactions precipitated on the cores of the granules in all 3 groups. Staining reactions were classified from 1+ to 5+ to designate increasing intensity. The first type, with the numerous 200 mμ granules, and the second type varied from 3+ to 5+ with the argyrophil reaction, but only from 1+ to 3+ with the argentaffin reaction. The third type, with the pleomorphic granules, showed heavy precipitations of 4+ and 5+ with the argentaffin reaction, and 4+ with the argyrophil reaction. It is concluded that all morphologic types of duodenal mucosal endocrine cells are positive for both argyrophil and argentaffin reactions; morphologic differences in secretion granules do not reflect differences in chemical nature; and that all endocrine duodenal cells are identical with respect to serotonin metabolism.

2416 ATROPHY OF VILLI WITH HYPERTROPHY AND HYPERPLASIA OF PANETH CELLS IN ISOLATED (THIRY-VELLA) ILEAL LOOPS IN RABBITS. LIGHT-MICROSCOPIC STUDIES. *(E.)* Keren, D. F.; Elliott, H. L.; Brown, G. D.; Yardley, J. H. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *Gastroenterology* 68(1): 83-93, 1975.

Thiry-Vella loops in albino rabbit ileum were prepared by a new technique and were studied for 18 hr to 49 days postisolation to determine morphological changes. Possible reversal of villus atrophy and other changes after reimplantation into the intestine or after repeated perfusion with nutrient substances were also investigated. Either 1 or 2 ileal segments, 10-15 cm long, were isolated by transecting the intestine at a point 30 cm proximal to the ileocecal valve. In the method used to create the Thiry-Vella loops, portions of Silastic tubing about 25 cm long were prepared with 3 circumferential beads of adhesive on the end of the tubing which was to receive the loop. One bead was placed at the end of the tubing, the second bead 0.5 cm proximal to the first, and the third bead (with attached 2.0 silk suture for anchoring the abdominal wall) 1 cm proximal to the second. Adhesive-prepared tubing ends were inserted in the ends of the isolated loop and the free ends were passed through a s.c. tunnel from the edge of the incision to the area of the scapulae where they were exteriorized through a 2-cm incision. In 18 animals with Thiry-Vella loops, the loops became grossly shortened after 14 days. Histologically, some shortening and blunting of villi was detectable as early as 4 days postisolation; with prolonged isolation the changes became marked. Reduction in epithelial cell height and in brush border thickness was noted, and goblet cells were increased somewhat in size and prominence. There was only slightly increased chronic inflammation in the mucosa and acute inflammation was uncommon, suggesting that mucosal injury was minimal. Mean epithelial mitotic indices for the crypts did not rise and were generally reduced. Hyperplasia and hypertrophy of Paneth cells associated with mitotic figures in Paneth cells accompanied the atrophic changes in the villi. Reimplantation of loops into the bowel 3 weeks after isolation led to complete reversal of all changes, including hyperplasia of Paneth cells. Regular perfusion of loops with a solution containing a large variety of nutrient substances failed to reverse the mucosal changes. It is concluded that atrophy of villi in isolated ileum of the rabbit occurs mainly because 1 or more substances contained in the chyme are needed to maintain normal mucosal architecture. These substances probably help regulate epithelial cell turnover and may well be endogenous in origin. Loss of substances in the chyme after loop isolation may also have led to Paneth cell hyperplasia or the Paneth cell changes and atrophy of villi may be related in a cause-and-effect manner.

2417 EFFECT OF HYPOTHYROIDISM ON QUANTITATIVE FEATURES OF LIVER CELLS AND THEIR NUCLEI: A MORPHOMETRIC AND CYTOPHOTOMETRIC STUDY OF RAT LIVER CELLS THREE WEEKS AFTER THYROIDECTOMY. *(Ger.)* Riede, U. N.; Schmitz, E.; Robausch, T.; Kiefer, G.; Grunholz, D.; Sandritter, W. (Pathol. Inst., Univ. Freiburg/Breisgau, Germany). *Beitr. Pathol.* 154(2): 140-160, 1975.

Thyroidectomies were performed on 15 male Wistar rats weighing 80 g; five sham-operated rats served as controls. After 21 days the rats were sacrificed and cytophotometric and morphometric studies were performed on their livers. In thyroidectomized rats, determination of the relative DNA contents showed that the ratio of diploid to tetraploid cells was 9:1, while in controls this ratio was 6:4. Thyroidectomy reduced the volumes of individual cells and their nuclei by half and doubled the volume of nucleoli. The average number of nucleoli/cell was 4 in both groups of rats. Thyroidectomy reduced the mitochondrial volume/nucleus by about 30% and decreased the number of mitochondria/nucleus by almost 50%. A 40% increase occurred in the area of the external membranes of the mitochondria, while the area of crista membranes/U mitochondrial volume decreased by 25%, the area of crista membranes/nucleus by 33%, and the number of mitochondrial granules/U mitochondrial volume by 50%. Thyroidectomy doubled the volume of peroxisomes and reduced the volume and number of peroxisomes/nucleus and the number of peroxisomes/U cytoplasm volume by about 25%. The volume of free ribosomes/nucleus decreased greatly. The relative volume of lysosomes/U volume of cytoplasm and nucleus decreased by 50%, while the number of lysosomes/nucleus and U volume of cytoplasm decreased by almost 90%. The volume of the rough endoplasmic reticulum decreased without any change occurring in the area of its membrane, suggesting that the lumen of each cisterna had narrowed. Similar changes have been observed in starvation. The relative volume of the smooth endoplasmic reticulum increased relative to the cytoplasm but not relative to the nucleus. These changes are attributed to reduced cellular metabolism in hypothyroidism.

2418 LAPAROSCOPIC AND MORPHOLOGICAL ASPECTS OF SUPERFICIAL LYMPHATIC VESSELS IN THE LIVER.

(Ger.) Meyer-Burg, J.; Mielke, F.; Arbeiter, G. (Steglitz Clin., Free Univ., Berlin, Germany). *Leber Magen Darm* 4(6):280-291, 1974.

After a review of the normal anatomy of lymphatics in the liver capsule, changes these vessels undergo in liver disease are described and methods for visualizing them are discussed. Superficial lymphatics can be seen in the normal liver at laparoscopy. Their absence is an indication of diffuse metastases in the liver of advanced cirrhosis. Apart from the upper and lower surfaces of the left and right convexities, lymphatics can also be observed in the falciform ligament of the liver and gallbladder wall. In fatty liver and acute and chronic hepatitis, lymph vessels are increased in number, dilated and, in some cases, filled with more fluid than in normal livers. In portal hypertension the volume of lymph is increased, but the cross-section of lymph vessels is reduced as a result of cirrhosis. Lymphangiectasis is observed in the capsules of cirrhotic livers but, in contrast to lymph vessels in the hepatoduodenal, falciform, and coronary ligaments, their walls are not hypertrophied. Stenosis and dilatation of the lymph vessels are observed in chronic aggressive hepatitis. As in animal experiments, when a dye was injected under pressure directly into lymphatics on the surface of the liver, if there was not enough albumin in the lymph to bind with the dye, the dye emerged from the lymph vessels after several minutes. If the emerging lymph cannot be absorbed, ascites starts to form. Lymph cysts, which are actually fliud-filled pseudocysts ranging in size from a pinhead to a cherry, are present in normal livers but occur in larger numbers in cirrhosis. In extrahepatic obstructive jaundice, lymph vessels are filled with a yellowish-green fluid at laparoscopy. This results from retrograde filling of the lymphatics with substances normally found in the bile. Similarly, RBC have been found in the lymph system in cirrhosis due to the development of lymphovenous or venolymphatic shunts. Lymph vessels in the capsule of the liver can be visualized by indirect injection of dyes into the splenic and hepatic veins or by direct injection of dyes, contrast media, or ^{198}Au into superficial lymphatic vessels in the liver. In contrast to animal studies, which showed that patent blue is excreted from the biliary tract in rats, this dye is excreted *via* the lymphatics in man. This difference is probably species specific. Direct injection of ^{198}Au into the superficial lymphatics to visualize the retroperitoneal space is not of great diagnostic value since scintigraphic resolution is poor.

2419 PRESENCE OF CELLS COMBINING FEATURES OF TWO DIFFERENT CELL TYPES IN THE COLONIC CRYPTS AND PYLORIC GLANDS OF THE MOUSE.

(E.) Nabeyama, A. (Dep. Anat., McGill Univ., Montreal, Canada). *Am. J. Anat.* 142(4):471-484, 1975.

Cells combining features of two different cell types were found in the colonic crypts and pyloric glands of the mouse. Specimens of descending colon (1 cm above pelvic rim) and pyloric antrum (near duodenum) from Swiss albino mice were fixed in paraformaldehyde and glutaraldehyde, postfixed in osmium tetroxide, stained with uranyl acetate and lead hydroxide, and examined by electron microscope. The normal cell pattern in the colonic crypt base consisted of about 83% vacuolated cells (containing a few membrane bound, 0.8 μm wide spheroids enclosing some 5 nm thick threads and 7 nm particles); 13% mucous cells (containing a few membrane bound 0.8 m wide spheroid mucous globules packed with dense 8 nm dot-like particles); 4% entero-endocrine cells (containing relatively few spheroidal or irregular granules, 100-300 nm, and occasional bundles of filaments near the nucleus); and 0.5% caveolated cells (having long microvilli, prominent filaments, and deep surface invaginations). All were rich in free ribosomes and relatively poor in secretory material. However, occasional cells were found resembling the vacuolated cells but also containing entero-endocrine type granules. Other vacuolated-type cells were found containing mucous globules in addition to the normal vacuoles. These were rich in free ribosomes in both types only when the vacuoles predominated over the granules or mucous globules. The pyloric glands were composed of numerous mucous cells with a few entero-endocrine cells, and an occasional caveolated cell. However, cells were found containing both mucous globules and entero-endocrine type granules and filaments and abundant free ribosomes. Cells resembling caveolated cells were also found, that contained mucous globules. Scarcity of secretory material and abundance of free ribosomes are signs of cellular immaturity; therefore it is suggested that in the descending colon the vacuolated cells transform into either mucous or entero-endocrine cells, and in the pylorus the mucous cells transform into entero-endocrine cells or caveolated cells.

2420 ELECTRON MICROSCOPE STUDIES OF RAT LIVER AFTER ORAL ADMINISTRATION OF CHENODEOXYCHOLIC ACID.

(Ger.) Leuschner, U.; Neuenfeldt, H. U. (Cent. Intern. Med., Johann Wolfgang Goethe Univ., Frankfurt/Main, Germany). *Z. Gastroenterol.* 13(1):27-34, 1975.

To determine whether chenodeoxycholic acid (CDC) causes morphological changes in the liver, it was given to 5 groups of 5 young male Wistar rats each in doses of 20 mg/kg p.o. through a stomach tube every day for 5-60 days. Another group of 5 rats received 29 mg/kg CDC for 30 days and 60 mg/kg for 30 days. No ultrastructural changes were found in the livers of rats treated with CDC for 5 and 14 days. Of the 5 rats given CDC for 20 days, 2 had dilated bile capillaries and a decrease in the number of villi with an occasional increase in the smooth endoplasmic reticulum and slight swelling of the mitochondria. Similar findings were observed in all 5 rats given CDC for 30 days. When CDC was administered for 60 days, light vacuoles, surrounded by a simple membrane, were found in all 5 rats; the contents of these vacuoles resembled those of the sinusoids. The vacuoles varied in size and were detected in all of the rats, but were not present in all of the cells. Tripling the dose of CDC had no effect on the findings. Invaginations of the sinusoidal cell membrane, which varied in size, and many cystic dilatations of the intercellular spaces suggest that the vacuoles might have formed by invagination of the external cell membrane.

2421 EPITHELIAL PROLIFERATION IN THE PROXIMAL GASTROINTESTINAL TRACT OF THE RABBIT. *(Ger.)* Strauss, P.; Koburg, E. (Clin. Otorhinolaryngol., Univ. Dusseldorf, Germany). *Arch. Otorhinolaryngol.* 208(1):49-59, 1974.

^{3}H-Labeled thymidine was administered i.v. or i.p. to rabbits 30 min to 96 hr before animals were sacrificed, and its incorporation into DNA was measured by autoradiography in the soft palate, upper and lower surface of the tongue, esophagus, and duodenum. In all tissues studied, the duration of mitosis (M) was 1.5 hr, and the duration of DNA synthesis (S), 8 hr (7 hr in the duodenum). Considerable variations were observed in the duration of the G_1 period and the time required for a cell to migrate between the germinative layer and the area adjoining the area of desquamation (T). The minimal duration of the G_2 period was limited to 30 min for all tissues studied. Each mitosis is assumed to result in the production of 2 f_1 cells which are equal in their ability to develop. Examination of the basal layer was sufficient to calculate the duration of the cell cycle C which ranged from 14.2 hr in the duodenum to 45 hr in the esophagus. If the percentage of ^{3}H-labeled cells is known, only the order of magnitude of the renewal time can be estimated.

2422 LYSIS OF LIVER CELLS CONTAINING ALCOHOLIC HYALIN BY NEUTROPHILIC GRANULOCYTES - AN ELECTRON MICROSCOPE STUDY. *(Ger.)* Rumpelt, H. J.; Thoenes, W. (Inst. Cytobiol. Cytopathol., Univ. Marburg/Lahn, Germany). *Verh. Deutsch. Ges. Pathol.* (57):247-251, 1973.

The lysis of hepatocytes with alcoholic hyalin by neutrophilic granulocytes was studied by electron microscopy in biopsy material from patients with alcoholic liver cirrhosis. Neutrophilic granulocytes were found to establish contact over a large surface with the plasma membrane of the hepatocyte without any conspicuous changes in the adjacent hepatocellular or granulocytic cytoplasm. Then, the contact surfaces show more or less extended membrane defects which involve either the hepatocellular membrane, or additionally also the granulocytic membrane. These defect sites are zones in which hepatocellular and granulocytic cytoplasms are mixed with each other. The hyalin material is subsequently released from the destroyed hepatocyte and into the sinusoid. The findings indicate the leukotactic character of hyalin-containing hepatocytes with yet closed cell membrane. Once a leukocyte wall is formed, the hepatocyte membrane, and often even the granulocyte membrane are dissolved, and the hyalin-containing hepatocyte undergoes cytolysis without any preliminary morphological signs of cell death.

2423 MORPHOLOGY AND MEASUREMENTS OF THE SMALL INTESTINE MUCOSA IN NORMAL CHILDREN. *(E.)* Toccalino, H.; Iovannitti, C.; Gallardo, F. (Profesor Alejandro Posadas Polyclin., Haedo, Argentina). *Acta Gastroenterol. Latinoam.* 6(1):43-46, 1974.

ABSORPTION-EXCRETION-TRANSPORT

2432 INCREASED INULIN ABSORPTION FROM THE CAT STOMACH EXPOSED TO ACETYLSALICYLIC ACID.

(E.) Flemstrom, G.; Marsden, N. V. B. (Biomed. Cent., Univ. Uppsala, Sweden). *Acta Physiol. Scand.* 92(4): 517-525, 1974.

The absorption of the ^{14}C-labeled polysaccharide inulin from the stomach of the cat was studied to determine if molecular species sufficiently large to be antigenic could be absorbed from the gastric lumen after exposure to acetylsalicylic acid. Six ml of an isotonic solution containing 12.5 μCi inulin with 15 mM acetylsalicylic acid (pH 2.70, 86% unionized) were introduced into the stomach through a glass cannula in the pyloric wall. The experiment lasted 6 hr and the urine volume and ^{14}C activity were measured at hourly intervals. The absorbed inulin was rapidly excreted and accumulated in the urine in sufficient quantities for molecular weight distribution analysis. About 95% of the urinary inulin had a molecular weight greater than 2000 and only moderate molecular sieving of the instilled inulin (average molecular weight 5200) occurred. This suggests that larger molecular species than tested could be absorbed from the stomach. The instillation of ^{14}C-inulin in acetylsalicylic acid-free isotonic NaCl, however, also resulted in a smaller but significant inulin absorption. The latter was further considerably reduced if the inulin was not added together with the isotonic saline, but later (20 min) in a small liquid volume, suggesting that mere distension of the stomach causes a temporary increase of the permeability which, however, is much smaller than that after acetylsalicylic acid. The acetylsalicylic acid-induced increase in ^{14}C activity in the urine reached a maximum during the second hr after instillation and thereafter declined slowly. It is suggested that ^{14}C activity after the second hr is probably due to a reduction of the acetylsalicylic acid-induced permeability increase caused by the loss of acetylsalicylic acid from the lumen, that is, the acetylsalicylic acid effect is reversible. It is concluded that acetylsalicylic acid increases gastric absorption of saccharide molecules of a size previously reported to be sufficiently large to evoke immune reactions.

2433 ABSORPTION OF CARBOHYDRATES AND VITAMINS IN THE PRESERVED AND TRANSPLANTED SMALL INTESTINE.

(E.) Toledo-Pereyra, L. H.; Simmons, R. L.; Najarian, J. S. (Dep. Surg., Univ. Minnesota, Minneapolis). *Am. J. Surg.* 129(2):192-197, 1975.

The absorptive ability of the entire small intestine of adult mongrel dogs of either sex for carbohydrates and vitamins was studied after preservation for 24 hr by hypothermic pulsatile perfusion and allotransplantation. After transplantation, azathioprine (5.0 mg/kg/day) was given i.v. for 3 days and then reduced to 2.5 mg/kg/day i.v. until death. P.o. alimentation was begun by the seventh postoperative day. Dogs receiving small intestine perfused for 24-hr survived a mean of 23.7 days. The main causes of death were cachexia, rejection, and intestinal obstruction. The body weight decreased gradually to values of 30.3% from the control weight at 4 weeks postgrafting; no regain in body weight was noted. Anemia and hypoproteinemia were also present. In dogs with perfused small intestine allografts the absorption of D-xylose was significantly impaired in the first 3 weeks after transplantation. An improvement in absorption values was observed at 5 weeks post grafting. The absorption of vitamin A was also reduced during the first week post transplantation, but lower normal limits were reached at 3 weeks after transplantation. Dogs that survived more than 5 weeks had normal absorption patterns of vitamin A. Absorption of vitamin B_{12} was not significantly altered after transplantation, always remaining within normal limits. Dogs in which intestinal allograft rejection developed had a progressive decrease in the intestinal absorption patterns. Intestinal denervation and the use of immunosuppressive drugs are factors that are involved in the impairment of absorption of small intestine allografts. The interruption of lymphatic drainage apparently does not play a significant role in the poor absorptive capacity of the transplanted intestine because lymphatic regeneration occurs in an average of 2-3 weeks after surgery when the functional capacity of the small intestine was still impaired.

2434 EFFECT OF SODIUM, MANNITOL, AND MAGNESIUM ON GLUCOSE, GALACTOSE, 3-O-METHYLGLUCOSE, AND FRUCTOSE ABSORPTION IN THE HUMAN ILEUM.

(E.) Bieberdorf, F. A.; Morawski, S.; Fordtran, J. S. (Univ. Texas Southwest. Med. Sch., Dallas). *Gastroenterology* 68(1):58-66, 1975.

The kinetics of sugar absorption in the human ileum *in vivo* were studied in an effort to reconcile a discrepancy resulting from previous experimental findings, namely that active sugar absorption *in vitro* is absolutely dependent on the presence of Na ions on the luminal side of the mucosa but that previous *in vivo* studies in the ileum of rat, dog, and man have shown that active glucose absorption is almost as rapid from a Na-free mannitol solution as from a NaCl solution. Absorption of 3 actively transported sugars (glucose, galactose, and 3-O-methylglucose) having different apparent K_m values and of fructose (absorbed by a separate carrier-mediated process) were measured in the human ileum in normal adults of both sexes, 21-45 yr old, using constant perfusion techniques. Perfusion solutions contained NaCl or Na substitutes and a sugar. Perfusion rate was 15 ml/min. Mannitol substitution for Na resulted in a slight reduction (23%) in the active absorption of glucose. Mg substitution for Na resulted in a greater depression (45%) of glucose absorption. The apparent K_m for glucose absorption was increased when Na was replaced by Mg, but the maximal absorptive rate (V_{max}) was not altered. Mg did not depress glucose absorption or the apparent K_m for glucose transport when Na was present in the perfusion solution. Neither Na removal nor Mg had any effect on fructose absorption. Absorption of galactose and 3-0-methylglucose (low affinity sugars for the glucose carrier) was reduced by about 40-50% when mannitol replaced Na, but Mg substitution for mannitol in a Na-free medium did not further depress absorption of these sugars. The following conclusions were reached: 1) part of the discrepancy between previous *in vitro* and *in vivo* experiments was due to the type of test sugar (glucose *versus* glucose analogue) and the solute used to replace Na in the luminal solution; 2) Mg is more effective than mannitol in reducing Na concentration at the glucose transport site on the brush border; 3) luminal Na ions have an important effect on active sugar absorption in the human small intestine *in vivo* as they do *in vitro*; 4) there is a component of active sugar absorption (about 1/2) which appears to be independent of luminal Na ions *in vivo*.

2435 THE EFFECT OF ANGIOTENSIN ON ISOSMOTIC FLUID ABSORPTION BY THE RABBIT GALL-BLADDER IN VITRO. *(E.)* Leyssac, P. P.; Kristensen, L. O.; Christensen, P.; Frederiksen, O. (Univ. Inst. Exp. Med., Copenhagen, Denmark). *Acta Physiol. Scand.* 92(4):508-516, 1974.

Evidence that angiotensin II inhibits net fluid transport by the gallbladder when applied to the serosal side was examined in further detail using the gallbladders of female white rabbits. Angiotensin inhibited net fluid transfer at serosal concentrations between 10^{-9}-10^{-8} M. Maximum inhibition (about 25%) was obtained at a concentration of 5 x 10^{-9} M. No significant effect was demonstrable at concentrations of 10^{-10} M or lower, and the effect disappeared at higher concentrations (10 and 20 x 10^{-9} M). The inhibitory effect was due to a depression of the unidirectional Na^+-efflux (from mucosal to serosal side); Na^+-influx (from serosal to mucosal side) was unaffected. Maximum effective doses of angiotensin had no effect on transepithelial potential difference; ohmic resistance increased slightly (about 10%). The inhibitory effect of angiotensin was significantly reduced by incubating gallbladders with indomethacin (10 μg/ml) which effectively blocks prostaglandin biosynthesis. Addition of indomethacin alone had no effect on either net fluid transfer rate, potential difference, or ohmic resistance. It is concluded that angiotensin inhibits isosmotic fluid transport in the gallbladder by an effect on the active component of the transfer process. The data suggest that the effect is indirect and mediated, in part at least, by release of endogenous prostaglandins, or alternatively that indomethacin might interfere with the angiotensin receptor.

2436 KINETICS OF TAUROCHOLATE UPTAKE BY THE PERFUSED RAT LIVER. *(E.)* Reichen, J.; Paumgartner, G. (Dep. Clin. Pharmacol., Univ. Bern, Switzerland). *Gastroenterology* 68(1):132-136, 1975.

The uptake of taurocholate by the perfused liver of male SPF rats of the Sprague-Dawley strain was studied by the multiple indicator dilution technique using single injections of ^{14}C-labeled taurocholate and ^{99m}Tc-labeled albumin. The livers were perfused *in situ* at a mean perfusion rate of 1.85 ml/min/g liver and at a mean perfusion pressure of 11.5 cm of H_2O. During each of 5 experiments, 3 to 6 doses (75 to 25,000 nM) Na taurocholate, each labeled with 4 nCi of Na taurocholate 24-^{14}C were given. Prior to administration, each dose of taurocholate was mixed with 10 μCi [^{99m}Tc]albumin in erythrocyte-free perfusion solution and injected rapidly in a constant volume of 0.21 ml into the portal vein cannula. Albumin and ^{51}Cr-labeled erythrocytes were injected together at the beginning and end of each experiment to determine the intra- and extravascular space of the liver. Total hepatic venous outflow was collected in 2-sec intervals. Taurocholate was distributed into an extravascular space equivalent to that of albumin. The taurocholate dilution curves appeared to be related to the albumin curves in a single exponential manner for the whole range of doses studied. Analysis of the dilution curves revealed that the initial taurocholate uptake rate increased with increasing taurocholate dose in a nonlinear fashion, exhibiting saturation kinetics which obeyed the Michaelis-Menten equation. The erythrocyte space was 15.8% of the liver weight and did not change significantly throughout one perfusion. The albumin and taurocholate space were 8.4 and 8.5% of the liver weight, resp., and did not differ significantly. The initial maximal uptake was found to be 32.5 nM/sec/g liver, a value exceeding the maximal steady state capacity for excretion of taurocholate into the bile. The half-saturation constant was 90.6 nM/g liver. It is concluded that this system is operating far from saturation at physiological levels of bile acids in portal blood. It is also suggested that taurocholate binds to some receptor or carrier of the hepatocyte but under the conditions of this experiment, it is not possible to differentiate between concentrative transport, facilitated transfer, or simple diffusion with subsequent binding to an intracellular receptor.

2437 STUDIES OF INTESTINAL ABSORPTION UNDER PATHOLOGICAL CONDITIONS. III. EXPERIMENTAL STUDIES OF GLUCOSE ABSORPTION DISORDER CAUSED BY SODIUM LAURYL SULFATE. *(E.)* Sugimura, F. (Nihon Univ. Sch. Med., Tokyo, Japan). *Nihon Univ. J. Med.* 16(2):173-189, 1974.

Glucose absorption through the intestinal wall of adult male white rabbits which had been damaged by exposure to 5% sodium lauryl sulfate solution was studied *in vivo* using a portal blood collecting technique. The lower small intestine was ligated at 2 sites 30 cm apart, after which a heparin-coated catheter was inserted into a relatively thick branch of the portal vein draining blood through small branches coming from a segment of the intestine between the 2 ligatures. The portal blood was collected in 5-min samples for the duration of each experiment. Ten ml of 5% glucose solution was injected into the lumen of the lower small intestine between the 2 ligatures by syringe in 5 normal rabbits and the portal blood collected every 5 min to estimate sugar level. In 2 of the 5 animals, the portal blood drained out continuously for a relatively long time, 80 and 105 min. The blood sugar level increased gradually and almost linearly for about 70 min after the injection and remained almost on the same level thereafter. When 10 ml of 5% glucose was injected into the lower small intestine 60 min after the injection of 10 ml of 5% sodium lauryl sulfate, glucose absorption through the intestinal wall rose linearly for the duration of the experiment (70 and 95 min, in 2 of 5 rabbits injected), indicating a pattern corresponding to passive diffusion. When 10 ml of 5% glucose containing an additional 5% sodium lauryl sulfate was injected into the lower small intestine, glucose absorption rose parabolically up to a definite height and thereafter remained on the same level in 2 of 5 rabbits (portal blood flow lasted for 60 and 120 min). It is concluded that sodium lauryl sulfate causes changes not only in the structure of the intestine but also in the mechanism of intestinal absorption. It is further concluded that the portal blood collecting method makes it feasible to study intestinal absorption under physiological conditions with minimum autolysis and no or mild tissue damage.

2438 HEPATOCELLULAR UPTAKE OF TAUROCHOLATE IN THE DOG. *(E.)*

Glasinovic, J. C.; Dumont, M.; Duval, M.; Erlinger, S. (INSERM, Beaujon Hosp., Clichy, France). *J. Clin. Invest.* 55(2):419-426, 1975.

The uptake of taurocholate by the liver of the intact dog was studied by the multiple-indicator dilution method in 22 experiments involving eight dogs and the kinetic characteristics of the uptake process determined. ^{51}Cr-labeled RBC (vascular indicator), ^{125}I-labeled albumin (an extravascular reference), and [^{14}C]taurocholate were injected into the portal vein. Different doses of unlabeled taurocholate were included in the injection mixture which had a total volume of about 1 ml. Hepatic venous samples were taken every 2 sec from an outflow catheter; sampling rate ranged from 1.0-1.5 ml/sec. Two to four sets of dilution curves were obtained in the same animal, with an interval of at least 45 min. As a consequence of the hepatic uptake, the outflow recovery of [^{14}C]-taurocholate was much reduced when compared to that of albumin, but its recovery increased with increasing doses of taurocholate, suggesting a progressive saturation of the uptake process. The analysis of the dilution curves fitted a 3-compartment model system well. No return of the extracted taurocholate to the extracellular space could be detected. The initial space of distribution of taurocholate was 1.22 times greater than that of albumin. Analysis of the data for uptake was consistent with Michaelis-Menten kinetics. The calculated initial maximal velocity of uptake was 4.53 μM/sec/100 g liver and the dose yielding half-maximal velocity was 7.11 μM/100 g liver. The maximal velocity of uptake was about 6 times the known maximal capacity of biliary secretion of taurocholate in the dog. It is concluded that these results are consistent with the hypothesis that the uptake of taurocholate is carrier-mediated.

2439 CHANGES IN INTESTINAL ABSORPTION IN THE SWINE AFTER ACUTE IRRADIATION. *(Fr.)*

Remy, J.; Daburon, F.; Villiers, P. A.; Chenut, M. C.; Nizza, P. (Lab. Appl. Radiobiol., At. Energy Comm., Jouy-en-Josas, France). *Strahlentherapie* 148 (1):95-106, 1974.

Two groups of 4 Pitman Moore pigs each, aged 8-15 months, were exposed to γ-radiation from ^{60}Co. Those weighing 25-50 kg were given only water for 15 hr before exposure to 1500 rads and were maintained on water until they died, while those weighing 20-35 kg were given only water for 15 hr before exposure to 800 rads and received water for 3 days after irradiation. Animals in the first group received no protection, while those in the 2nd group were partially protected by lead plates over the body from the xyphoid process of the sternum to the occipital crest, permitting survival of 6-8% active bone marrow. Except for 1 pig given infusions of amino acids, minerals, and vitamins 21 days after irradiation, no treatment was given to either group. Within 1 hr after irradiation with 1500 rads, glucose absorption decreased to 3%, Ca absorption to 4%, and Na absorption to 11.7% of preirradiation values. Except for glucose absorption, which increased on day 2, these decreases persisted at about the same level until day 4. Irradiation with 800 rads also reduced glucose, Na, and Ca absorption, but this decrease was not as great and did not occur until 2-4 days after irradiation. Na and glucose absorption tended to increase again 2 weeks after irradiation, but Ca absorption remained below normal for several months in 1 pig although blood Ca levels remained within normal limits throughout the experiment. While irradiation with 800 rads did not produce a gastrointestinal syndrome in the swine, growth was completely arrested in 1 of the pigs for 4 months as a result of malabsorption.

2440 A PROPOSED MECHANISM FOR ZINC ABSORPTION IN THE RAT. *(E.)*

Evans, G. W.; Grace, C. I.; Votava, H. J. (Hum. Nutr. Lab., Agric. Res. Serv., US Dep. Agric., Grand Forks, N.D.). *Am. J. Physiol.* 228(2):501-505, 1975.

The uptake of zinc by the epithelial cell basolateral plasma membrane was studied, along with the effect of albumin on membrane-bound zinc. Labeled zinc was added to pancreatic secretions from a mongrel dog or to pancreatic supernatant from male Sprague-Dawley rats, after which zinc binding was measured. In other experiments, the whole-body absorption of ^{65}Zn was measured in rats in which the common bile duct or the hepatic duct was ligated, and the effect of the pancreatic zinc-binding ligand on zinc uptake by the intestinal epithelial cells was examined using everted small intestinal segments. Both the dog pancreatic secretions and the rat pancreatic supernatant fraction contained a low-molecular-weight ligand which bound zinc. The whole-body absorption of ^{65}Zn in rats in which the common bile duct was ligated was significantly less than that in normal animals or animals in which the hepatic bile duct had been ligated. Although jaundice was present in all ligated rats, it had no apparent effect on zinc absorption. When the zinc-binding ligand from the dog pancreatic secretions was added to a labeled buffer solution, the *in vitro* uptake by rat intestinal epithelial cells was significantly greater than that in buffer solution containing no ligand. Following *in vivo* labeling, 30% of the ^{65}Zn in the epithelial cells was associated with the partially purified basolateral plasma membrane. When labeled basolateral plasma membranes were incubated in a medium containing zinc-free albumin, approximately 96% of the ^{65}Zn was transferred to the medium; less than 30% of the isotope was released into media containing no albumin or a 3:1 zinc:albumin complex. In rats fed a zinc-deficient diet, ^{65}Zn absorption was inversely proportional to the serum zinc concentration, and both zinc and copper injections produced a marked decrease in ^{65}Zn absorption. These results suggest that zinc absorption consists of interactions among a low-molecular-weight ligand, receptor sites on the basolateral membrane, and metal-free albumin.

2441 BILIARY EXCRETION OF IODIPAMIDE. *(E.)*

Loeb, P. M.; Berk, R. N.; Feld, G. K.; Wheeler, H. O. (San Diego Sch. Med., Univ. California, La Jolla). *Gastroenterology* 68(3):554-562, 1975.

The dose and rate of iodipamide necessary for optimal biliary excretion with the least risk of toxicity were investigated. Three adult mongrel dogs had cholecystectomies and Thomas cannulas inserted in the duodenum opposite the duodenal papilla. Indwelling Silastic catheters in both external jugular veins were used for blood collections and infusions. Dogs were fasted for 24 hr before bile collection, and 0.5 mg/kg of pipenzolate methylbromide were initially administered i.v. followed by a dose of 0.1 mg/kg every 20 min to minimize bile flow fluctuations. An i.v. infusion of 1.5% sodium taurocholate solution was given throughout to replace bile salts lost. When bile flow was constant, control samples of blood and bile were collected, and a 15.3% solution of methylglutamine iodipamide was infused at 7 increasing rates between 0.33 and 7.33 μm/min/kg. After 30 min at each rate a 3 ml sample of bile was collected, a blood sample was collected at the midpoint of each collecting period, and iodine concentrations of both were measured. In 2 experiments, urine was also collected, and its iodine concentration determined. When the infusion rate of iodipamide was increased stepwise from 0.33 to 4.0 μm/min/kg, the plasma concentration increased in a linear fashion from 0 to 0.83 μm/ml. At 7.33 μm/ml/kg, the plasma concentration rose at a slower rate. The rate of excretion and concentration of the drug in the bile increased markedly at lower plasma concentrations and began to plateau when the plasma concentration reached 0.4 to 0.6 μm/ml. As the iodipamide infusion rate was increased, biliary iodipamide excretion increased sharply up to an infusion rate of 2 μm/min/kg after which progressively smaller increments of the drug were excreted. The drug did not appear in the urine until the plasma concentration had reached 0.20 m/ml, after which the rate of excretion in the urine increased in a linear fashion. At a plasma concentration of 0.20 the ratio of biliary to urinary excretion was 14, while at a plasma concentration of 0.60 the ratio was less than 2. When a steady state of plasma concentration and biliary excretion was reached at each constant iodipamide infusion rate, the total excretion rate of the drug in bile and urine was less than the rate of infusion. The excretory deficit increased as the plasma concentration increased. It is concluded that by slow infusion, high plasma concentrations could be avoided, and the smallest dose necessary for radiographic visualization could be given.

2442 THE EXSORPTION CHARACTERISTICS OF VARIOUS SUGARS. *(E.)*

Axon, A. T. R.; Creamer, B. (St. Thomas' Hosp., London, England). *Gut* 16(2):99-104, 1975.

The exsorption patterns of glucose, galactose, xylose, mannose, and lactulose from rabbit plasma to intestinal lumen were compared. Each sugar was injected *via* external cannula into the jugular vein in a solution containing 1 g of creatinine. After a 15-min equilibration period, intestinal perfusate was collected for a 10-min period and the concentrations of the test substance in the plasma and perfusate were determined using quantitative paper chromatography. With lactulose, mannose, and xylose, there was a direct relationship between exsorption rate and plasma concentration. The intestinal clearance of xylose was significantly greater than that of mannose or lactose; the latter two did not differ significantly in this respect. At low concentrations there appeared to be a barrier preventing glucose and galactose from reaching the lumen; virtually no exsorption took place until the plasma concentration reached 50 μM/ml, and even at 100 μM/ml exsorption was slow. When the plasma concentration was increased, however, the exsorption rate increased considerably. Phlorizin (10^{-2} M) completely abolished the mucosal barrier to glucose; luminal glucose (140 μM/ml) had a similar effect on galactose exsorption. 2,4-Dinitrophenol had no effect on the exsorption of glucose, and removal of sodium from the luminal perfusate had no effect on galactose exsorption. The data suggest that there are two barriers which prevent actively absorbed monosaccharides from passing from plasma to lumen: an anatomical one which restricts all large water-soluble molecules to some extent; and a specific barrier which is related to the active absorption mechanism.

2443 INFLUENCE OF DEHYDROCHOLATE AND TAUROCHOLATE ON BROMSULPHTHALEIN UPTAKE, STORAGE,

AND EXCRETION IN THE DOG. *(E.)* Delage, Y.; Erlinger, S.; Duval, M.; Benhamou, J. P. (INSERM, Beaujon Hosp., Clichy, France). *Gut* 16(2):105-108, 1975.

The influence of dehydrocholate on bromsulphthalein relative-storage capacity, biliary transport maximum, and fractional transfer rates between plasma, liver, and bile were studied in unanesthetized mongrel dogs. In six dogs, storage capacity, biliary transport maximum, and fractional transfer rates from plasma to liver, liver to bile, and liver to plasma were measured during 0.15 M NaCl infusion. The measurements were repeated under a dehydrocholate infusion of 95 μM/min, an infusion rate approaching the known biliary transport maximum of bile salts. The storage capacity and fractional transfer rates from plasma to liver were significantly lower during dehydrocholate infusions (18 mg/mg/100 ml and 0.120 mg/mg/min, resp.) than during NaCl infusions (47 mg/mg/100 ml and 0.280 mg/mg/min, resp.). The transport maximums and fractional transfer rates from liver to bile were also significantly lower during dehydrocholate infusions (3.2 mg/min and 0.013 mg/mg/min, resp.) than during NaCl infusions (4.8 mg/min and 0.033 mg/min, resp.). In three additional experiments, taurocholate had similar effects to those of dehydrocholate on storage capacity and transport maximum. These findings suggest that competition occurred between the bile salts and bromsulphthalein from hepatic uptake and storage. They support the hypothesis that the decreased disappearance rate and relative storage capacity of bromsulphthalein observed during biliary obstruction may be due to competition between bile salts and bromsulphthalein for hepatic uptake and storage.

2444 **EFFECT OF DIETARY LACTOSE ON THE ABSORPTION OF PROTEIN, FAT AND CALCIUM IN THE POST-WEANING RAT.** *(E.)* Leichter, J.; Tolensky, A. F. (Div. Hum. Nutr., Sch. Home Econ., Univ. British Columbia, Vancouver, Canada). *Am. J. Clin. Nutr.* 28(3):238-241, 1975.

The effect of different dietary levels of lactose on the excretion of protein, fat, and calcium was studied in the postweaning rat, which has a low level of intestinal lactase activity. Young male Sprague-Dawley rats were maintained for 13 days on diets containing 10% lactose, 30% lactose, 10% sucrose, or 30% sucrose. Food intake, weight gain, and the fecal and urinary excretion of protein, nitrogen, and calcium were monitored over the last 10 days. The 30% lactose group showed the lowest food intake, lowest weight gain, and lowest food efficiency. The urine volume in the two lactose groups was significantly higher than in the sucrose groups. The fecal fat and nitrogen excretions were also significantly higher in the lactose groups, but the fecal calcium was lower in the lactose groups; the latter difference was significant only in the case of the 30% lactose group. The lactose and sucrose groups did not differ significantly in urinary nitrogen excretion, but urinary calcium excretion was significantly higher in the 30% lactose group. These findings suggest that dietary lactose may reduce the absorption of protein and fat, but not of calcium, in individuals with low levels of intestinal lactase activity.

2445 **INTESTINAL TRANSPORT OF TRYPTOPHAN AND ITS ANALOGS.** *(E.)* Bosin, T. R.; Hathaway, D. R.; Maickel, R. P. (Med. Sci. Program, Indiana Univ., Bloomington). *Am. J. Physiol.* 228(2):496-500, 1975.

The role of the indole nucleus in the active intestinal transport of tryptophan and its 1-methylindole and benzo(b)thiophene analogs was studied *in vitro* in the rat and hamster. Everted intestinal sacs prepared from adult male Sprague-Dawley rats and adult male golden hamsters were filled with test solutions containing tritium-labeled D,L-tryptophan or one of its analogs. Both tryptophan and tryptophan-benzo(b)thiophene were actively transported across the intestinal tissues, while tryptophan-1-methylindole was not actively transported. There was no significant difference between the K_m and maximal transport velocity (V_{max}) values or between, resp., K_m and V_{max} values of the former two when compared between rat and hamster. Tryptophan transport in the rat was competitively inhibited in the presence of the benzo(b)thiophene analog, while the 1-methylindole analog was unable to inhibit tryptophan transport. The transport of tryptophan and its benzo(b)thiophene analog was depressed at high concentrations (10 M), and all three amino acids produced subtle alterations in the barrier properties of the intestinal sacs, as evidenced by increased tetraethylammonium $[^{14}C]$-bromide diffusion. The results indicate that tryptophan and its benzo(b)thiophene analog share the same carrier and interact in a competitive fashion, while the 1-methylindole analog appears to be inert with respect to carrier interaction. The results also indicate the importance of the 1-position of the indole nucleus as a site for steric interaction of tryptophan with the carrier molecule.

2446 **SITES OF ORGANIC ACID PRODUCTION AND ABSORPTION IN GASTROINTESTINAL TRACT OF THE PIG.** *(E.)* Argenzio, R. A.; Southworth, M. (Dep. Physiol. Biochem. Pharmacol., New York State Vet. Coll., Cornell Univ., Ithaca). *Am. J. Physiol.* 228(2):454-460, 1974.

The effect of diet and time elapsed after feeding and the pH and production of volatile fatty acids in the gastrointestinal tract was studied in the pig. Growing pigs were maintained on a commercial diet containing 20% protein or on a high-cellulose, low-protein diet containing 3% protein and 3% urea. On the day of the experiment, the animals were killed 2, 4, 8, or 12 hr after the morning meal and the pH and volatile fatty acid content in their gastrointestinal tracts determined. In parallel studies, the *in vitro* absorption of volatile fatty acids was measured in samples of large intestinal and stomach mucosa from pigs on the commercial diet. In animals fed the control diet, the contents of the cranial half of the stomach showed marked, cyclic fluctuations in pH and high concentrations of organic acids. The contents of the caudal (glandular) half were lower in both pH and organic acid concentration. Despite concentrations of volatile fatty acids as high as 250 mEq/liter in the large intestine, the pH remained relatively neutral. The volatile fatty acid levels remained relatively constant throughout the length of the colon. In the animals fed the low-protein, high-cellulose diet, there was no weight gain. The pH of the gastric and duodenal contents was lower and that of the remaining small and large intestinal contents was higher than in the controls. Concentrations of the volatile fatty acids in the gastric and large intestinal mucosa were considerably lower than in the controls. In the *in vitro* studies, all four types of gastric mucosa absorbed and transported volatile fatty acids at substantial rates, although the cecal and colonic mucosa transported these acids at much greater rates than the gastric mucosa, the equine large intestinal mucosa, or the bovine rumen epithelium. The results suggest that: 1) substantial amounts of carbohydrate undergo microbial digestion in the stomach and large intestine of pigs fed a high-concentrate growing ration; 2) the volatile fatty acids are readily absorbed and may provide an important source of energy; and 3) that the production and absorption of these fatty acids may have a major effect on the secretion and absorption of sodium and water by the large intestine.

2447 RESPONSE OF ACTIVE TRANSPORT OF IONS AND SPONTANEOUS WATER FLUX TO OSMOTIC GRADIENTS IN GASTRIC MUCOSA. *(E.)* Villegas, L. (Cent. Biophys. Biochem., Venezuelan Inst. Sci. Invest., Caracas). *Am. J. Physiol.* 228(3):738-741, 1975.

The effects of symmetric changes in the mucosal and serosal bathing solutions on cell water content, net ion flux, and net water movement were studied in the isolated frog gastric mucosa. Mucosas from *Rana pipiens* were bathed in hyposmotic (165 mOsm/kg water), buffered hyposmotic, isosmotic (226 mOsm/kg water), or hyperosmotic (286 mOsm/kg water) solutions. There was a linear correlation between cell water content in the mucosa and osmolality of the solutions. A similar correlation was found between cell water content and osmolality of the nutrient solution. While there was a significant correlation between the observed net water flux and osmolality, there was no significant correlation between the transmucosal potential difference and the osmolality of the solution. Similarly, acid secretion was significantly correlated with osmolality, but short-circuit current, transmucosal potential difference, and conductance were not. It is postulated that similar effects on spontaneous ion and water fluxes might occur if the tonicity were changed only at one surface rather than both. The data obtained question the validity of measuring transmucosal osmotic permeability without making appropriate corrections for the changes in spontaneous fluxes related to cell osmolality changes such as those observed in the absence of transmucosal osmotic gradients.

2448 STIMULATION OF ACTIVE AND PASSIVE SODIUM ABSORPTION BY SUGARS IN THE HUMAN JEJUNUM. *(E.)* Fordtran, J. S. (Univ. Texas Health Sci. Cent. Dallas, Southwest. Med. Sch.). *J. Clin. Invest.* 55 (4):728-737, 1975.

The effects of glucose and fructose on water and sodium absorption in the human jejunum were compared to assess the relative contributions of the active and passive sugar stimulation of sodium transport. The effect of fructose was assumed to be entirely passive, and the difference between the effects of fructose and glucose was assumed to be a measure of sugar-stimulated, active sodium absorption. Nine normal subjects were studied with the triple-lumen perfusion system; water and electrolyte movement with mannitol served as a base line for quantitating the effects of fructose and glucose. At 130 mM sugar, glucose and fructose stimulated water and sodium absorption equally/mM sugar absorbed. Under conditions where glucose and fructose were absorbed at approximately equal rates, the stimulated rates of water and sodium absorption/mM sugar absorbed were about 30% lower with fructose than with glucose. The two sugars stimulated chloride absorption to approximately the same extent and in proportion to the stimulated water and sodium absorption rates. Glucose, however, stimulated more chloride absorption/mM sugar absorbed than did fructose. Compared with fructose, glucose had a 20-30% greater effect on the absorption of urea. Glucose stimulated potassium secretion and fructose stimulated potassium absorption. Neither sugar significantly affected sodium movement when bicarbonate or sulfate, rather than chloride, was the major anion present in the perfusing solution. It is concluded that glucose stimulates passive and active sodium transport in the human jejunum. Stimulated active sodium absorption generates an electrical potential across the mucosa that causes sodium and potassium secretion and partly or completely nullifies the effect of active sodium transport on net sodium movement. Net sodium absorption stimulated by glucose is mainly the passive consequence of solvent flow. The accompanying anion determines the degree to which sugars stimulate sodium absorption. The effects of bicarbonate and sugars on jejunal sodium absorption are not additive.

2449 EFFECTS OF UNILATERAL SODIUM REPLACEMENT ON SUGAR TRANSPORT ACROSS IN VITRO RABBIT ILEUM. *(E.)* Rinaldo, J. E.; Jennings, B. L.; Frizzell, R. A.; Schultz, S. G. (Univ. Pittsburgh Sch. Med., Pa.). *Am. J. Physiol.* 228(3):854-860, 1975.

The effects of unilateral sodium replacement in the perfusion medium on the passive and active transport of 3-*O*-methyl-D-glucose across the isolated rabbit ileum were studied, using choline chloride and mannitol in place of sodium. Replacement of sodium in the serosal solution alone did not significantly affect the net passive movement of 3-*O*-methyl-D-glucose from the mucosal solution to the serosal solution. However, when sodium was replaced in the mucosal solution alone, the net passive absorption of 3-*O*-methyl-D-glucose did not differ significantly from that observed when both the mucosal and serosal solutions were rendered sodium-free. The results with choline chloride were nearly identical with those obtained with mannitol. The presence or absence of sodium in the serosal solution did not significantly affect the rate of active 3-*O*-methyl-D-glucose absorption, while replacement of sodium in the mucosal solution inhibited sugar absorption. The results did not differ significantly when sodium was replaced with choline or mannitol. There was good agreement between the bi-directional fluxes of mannitol and 3-*O*-methyl-D-glucose when the mucosal solution alone was rendered sodium-free by replacement with choline. The results indicate that replacement of sodium in the mucosal solution alone essentially abolishes transcellular 3-*O*-methyl-D-glucose transport and that the remaining transepithelial fluxes are largely due to diffusion through the paracellular or shunt pathway.

2450 EFFECT OF ETHANOL INGESTION ON DUODENAL CALCIUM TRANSPORT. *(E.)*

Krawitt, E. L. (Dep. Med., Univ. Vermont, Burlington). *Lab. Clin. Med.* 85(4):665-671, 1975.

The effect of ethanol and duodenal calcium transport and the concentrations of intestinal proteins was studied. Male albino rats were given 20% ethanol as the sole source of fluid for 12 days; in some cases the rats had been raised on a vitamin D-free diet. Vitamin D and 25-hydroxycholecalciferol were administered i.p. or intragastrically 24 hr before death. The chronic ingestion of ethanol resulted in a significant depression of calcium transport by everted duodenal gut sacs. The administration of vitamin D_2, D_3, or 25-hydroxycholecalciferol did not completely restore the ability of the gut sacs to transport calcium. In rats fed a vitamin D-deficient diet, ethanol did not affect the serosal:mucosal ratios when compared to vitamin D-deficient controls, nor did it interfere with the ability of pharmacologic doses of vitamin D to increase the rates of transport when given 24 hr before experimentation. Ethanol ingestion caused a decrease in the protein concentration in the duodenal 38,000 x g supernatant, but did not significantly affect the calcium-binding activity. Ethanol also depressed the activity of duodenal alkaline phosphatase; this activity was restored to normal levels by vitamin D administration 24 hr before death. Duodenal alkaline phosphatase activity was also depressed in starved, non-ethanol-treated rats. Ethanol ingestion did not significantly affect ATPase activity. The results suggest that ethanol interferes with calcium transport by a mechanism at least in part independent of the vitamin D pathway and that changes in alkaline phosphatase and calcium transport, although both affected by vitamin D, may represent independent metabolic consequences.

2451 THE ABSORPTION AND SUBSEQUENT UTILIZATION OF LECITHIN BY THE RAT JEJUNUM. *(E.)*

Rodgers, J. B.; O'Brien, R. J.; Balint, J. A. (Dep. Med., Albany Med. Coll., NY). *Am. J. Dig. Dis.* 20 (3):208-213, 1975.

The utilization of luminal lecithin for the synthesis of microsomal and prochylomicron-chylomicron lecithin was studied during a period when the intestine was actively absorbing dietary lipid. Bile fistula male Sprague-Dawley rats were infused with a mixture of liquid diet, sodium taurocholate and lecithin at a rate of 2.4 ml/hr; bile salts and labeled lecithin were added to the liquid diet on the day of use. The animals were killed and samples of intestinal microsomes and intestinal prechylomicrons plus chylomicrons obtained. The specific activities of the isotopes in lecithin were determined using liquid scintillation spectrometry. After 1 hr, significant quantities of the three isotopes were present in the microsomal lecithin. Less radioactivity was recovered from the prechylomicron-chylomicron lecithin than from the microsomal lecithin, ^{32}P being particularly reduced in the former. Total recoveries of lecithin were much greater from the microsomal fraction (3.94 mg) than from the prechylomicron-chylomicron fraction (0.53 mg); thus, the specific activities of ^{3}H and ^{14}C were uniformly greater in the latter. The ratio of glycerol to palmitate in the microsomal and prechylomicron-chylomicron fractions was very similar to the ratio in the original lecithin, as was the glycerol:phosphate ratio in the microsomal fraction. The results indicate that luminal lysolecithin formed by the hydrolysis of lecithin by pancreatic phospholipase can be absorbed without further digestion and reutilized for mucosal lecithin synthesis. They also suggest that when sufficient lysolecithin is present in the intracellular compartment, the major pathway for lecithin synthesis is *via* acylation of this substrate, and that the major role of lysolecithin absorbed from the intestinal lumen after lecithin digestion is for lipoprotein production.

2452 REGULATION OF INTESTINAL CALCIUM-BINDING PROTEIN BY CALCIUM INTAKE IN THE RAT. *(E.)*

Freund, T.; Bronner, F. (Univ. Connecticut Health Cent., Farmington). *Am. J. Physiol.* 228(3):861-869, 1975.

The effect of dietary intake on the rat intestinal calcium-binding protein was studied. Male Sprague-Dawley rats were maintained on semisynthetic diets containing 0.06% calcium and 0.2% phosphorus, 1.5% calcium and 1.5% phosphorus, 0.5% calcium and 0.5% phosphorus, or 1.5% calcium and 0.2% phosphorus. All diets contained 2,200 IU/kg vitamin D_2. In addition, some animals were maintained on diets similar to the latter two, but with no added vitamin D_2. The calcium-binding protein of the intestinal mucosa of these animals was assayed using analytical gel electrophoresis. The binding capacity of the calcium-binding protein was significantly higher in the material obtained from the animals fed the low calcium diet than in that from the animals fed the high calcium diet. The binding activity from rechromatographed calcium-binding protein existed as two bands on polyacrylamide electrophoresis. In material from the animals on the low calcium diet, there was little activity in the form of band 1, whereas in the material from the animals on the high-calcium diet, more than half was in the form of band 1. Both bands were vitamin D-dependent. When animals on the high-calcium diet were placed on a low calcium diet, their calcium-binding protein concentration increased by

35% within 24 hr and by 48% within 48 hr, by that time reaching a level typical of animals on a low-calcium diet. Measurement of the diurnal variation in calcium-binding protein and mucosal calcium in animals allowed access to feed only at night, revealed significant inverse oscillations. The results suggest that the calcium-binding capacity (i.e., calcium-binding protein) is an inverse function of the calcium concentration of the mucosal tissue, which, in turn, appears to reflect absorbed calcium in transit.

2453 ANALYSIS OF THE COMPONENTS OF BILE FLOW IN THE RHESUS MONKEY. *(E.)* Strasberg, S. M.; Ilson, R. G.; Siminovitch, K. A.; Brenner, D.; Palaheimo, J. E. (Dep. Surg., Univ. of Toronto, Canada). *Am. J. Physiol.* 228(1):115-121, 1975.

The components of bile flow was studied in three groups of rhesus monkeys. In the first group the clearance of [^{14}C]-erythritol was shown to be a canalicular process by using monkeys that had the bile flow diverted externally and who had been given [^{14}C]-erythritol (0.02 µCi, infused by peristaltic pump), sodium taurocholate (10 mM/day, i.v.), and secretin (20 U/hr, i.v.). Flow, canalicular clearance, bile salt secretion, and bicarbonate secretion were studied in a second group of monkeys after resection of the gastric antrum and small bowel. These animals were given sodium taurocholate (6-10 mM/day i.v.), and erythritol-^{14}C (0.01 µCi/min steady infusion). Canalicular clearance of erythritol was shown to be equal to canalicular flow. Ductular reabsorption was constant at all bile salt secretion rates in the individual animal, and bicarbonate secretion was dependent on bile salt secretion. In group 3 bile flow, bile salt secretion, bicarbonate secretion and canalicular flow were studied over a 2 week period while the animals received intraduodenal sodium taurocholate (3-10 mM/day) and labeled (0.01 µCi/min) and unlabeled erythritol (6-10.0 mM/day) during feeding and fasting. The variability in bile flow in the fasting animal at one bile secretion rate was linearly related to bicarbonate secretion. A multivariate regression model was proposed to describe bile flow in the rhesus monkey based on these study groups. This model enabled the authors to show that the variations in the relationship between bile flow and bile salt secretion rate, in the fasting animal, were due to ductular flow, related to the secretion of bile salt-independent bicarbonate.

2454 ELECTROPHYSIOLOGY OF THE FROG GASTRIC MUCOSA WITH SUFFICIENT CO_2. *(E.)* Kidder, III, G. (Sch. Dent., Univ. Maryland, Baltimore). *Am. J. Physiol.* 228(3):928-933, 1975.

Electrophysiological parameters were compared in bullfrog gastric mucosa perfused with a solution containing 5% CO_2 (standard) and 10% CO_2 (for maximum acid secretion), in the gaseous phase. The mucosa was removed, mounted in a chamber, and perfused with bicarbonate-Ringer solution on the serosal surface and similar but unbuffered solution on the mucosal surface. Acid secretory rate was measured by the pH-stat method, and potential difference by KCl/calomel reference electrodes. Measurements were made during the last 30 min of a 1 hr experimental period. Tissues were exposed either to the 5% or the 10% solution. The secretory rates were 2.17 and 4.44 µEq/cm^2/hr for the 5% and 10% CO_2 solutions, resp. Secretory lag (time between readmission of O_2 after a 20 min anaerobic period, and the rise of the secretory rate to 50% of the maximum) was 6.56 and 8.44 min for the 5% and 10% solutions, resp. Potential differences were 22.2 and 31.5 mV, resp. Secretory overshoot (ratio of peak secretory rate on reoxygenation to the steady-state rate during the following hr) was 125% and 105% of steady state, resp. All differences were statistically significant. Tissues subjected to 1 hr of anoxia during preparation showed an unexpected sudden potential drop (11 to -1 mV in 1 min) when exposed to the 10% solution; a normal potential decrease to 7.3 mV in 1 min occurred with the 5% solution. For 21 tissues, after 1 hr of anoxia the sudden potential drop occurred 35.0 min after anoxia for 14-58 min at 8.2 mV. On reoxygenation, the potential difference rose at 7.0 min and the secretory lag was 21.7 min. It is concluded that removal of CO_2 as a limiting factor by using a 10% concentration has effects on parameters other than acid secretion, including a sudden potential drop completely new to these conditions.

2455 REDUCTION OF CALCIUM ABSORPTION DUE TO DIVERSE INHIBITORS OF ALKALINE PHOSPHOMONOESTERASE. *(Fr.)* Fournier, P.; Dupuis, Y.; Digaud, A.; Fournier, A. (Fac. Pharm. Biol. Sci. Chatenay-Malabry, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 279(6): 497-500, 1974.

After an overnight fast, male Wistar rats were given 2ml of various calcium solutions containing 0.1 µCi of ^{45}Ca/ml p.o. through a stomach tube. Plasma radioactivity was measured after 3 hr, and the animals were sacrificed after 5 or 24 hr. The ^{45}Ca content of a femur, digestive contents and feces (collected from the start of the experiment) was determined. Absorption and retention values for calcium gluconate solutions were up to 5 times higher than for calcium glycerophosphates, while calcium chloride values fell in between. The glycerol portion of the glycerophosphates had no effect on calcium absorption, but the phosphate moiety inhibited absorption in proportion to the amount of phosphate present. It is proposed that alkaline phosphatase acts as a calcium-binding protein whose effect is inhibited in the presence of phosphate ions and enhanced in the presence of sugars.

2456 FUNCTION AND STRUCTURE OF THE MUCOSA OF CONTINENT ILEOSTOMY RESERVOIRS IN DOGS. *(E.)* Philipson, B.; Kock, N. G.; Robinson, J. W. L.; Menge, H.; Mirkovitch, V. (Sahlgrenska Hosp., Univ. Goteborg, Sweden). *Gut* 16(2):132-136, 1975.

Morphological changes and absorptive capacity were studied in continent ileostomy reservoirs in the dog. Nineteen mongrel dogs had the ileum divided about 7 cm from the ileocecal valve, and the distal stump closed. A loop of ileum was constructed into a pouch, fixed in the abdomen, and the outlet passed through the abdominal wall to create an ileostomy. A catheter was inserted before closure for volume registration and drainage. After 3-4 days the permanent cahteter was removed and the reservoir emptied 3 times daily by insertion of a catheter. After 9-29 days the reservoir was emptied, its volume was determined by saline insufflation, and it was removed with 50 cm of proximal small intestine. Tissue samples were cut parallel to the villus/crypt axis, and fixed and stained. Samples of mucosa were also separated from the muscle and incubated for 1 hr in ^{14}C-labeled L-phenylalanine or β-methyl-D-glucoside, and other samples were incubated with ^{14}COOH-inulin to determine extracellular space. Oxygen consumption and acid phosphatase release were determined after incubation in Krebs phosphate buffer containing 2 mg/ml glucose. Of 19 dogs, 8 survived long enough for characteristic changes to occur in the reservoir. In these the mean volume of the reservoirs had increased by 280 ml. The villi were fingerlike and shorter than normal with occasional mosaic forms. Morphometric evaluations showed also an increase in villous width and a reduction in epithelial cell height. The mitotic index of the reservoir mucosa was 3.05 while that of the proximal intestine was 2.25, a significant difference. There was a significant reduction of phenylalanine and β-methyl glucoside transport in the mucosa of the pouch and the proximal intestine, but no significant difference between these 2 areas. Oxygen consumption and phosphatase release were both lower than control values, but the same for both reservoir and proximal intestine. Results suggest that the reservoir mucosa undergoes a hyperregenerative transformation from the exogenous stress of its contents, and the number of active absorbing cells is reduced.

2457 AN EXPERIMENTAL METHOD OF IDENTIFYING AND QUANTIFYING THE ACTIVE TRANSFER ELECTROGENIC COMPONENT FROM THE DIFFUSIVE COMPONENT DURING SUGAR ABSORPTION MEASURED IN VIVO.

(E.) Debnam, E. S.; Levin, R. J. (Dep. Physiol., Univ. Sheffield, England). *J. Physiol. (Lond.)* 246(1):181-196, 1975.

The kinetics of active sugar transport in the rat jejunum were measured *in vivo* using the traditional chemical techniques together with a new method utilizing the electrical potential difference generated across the intestine by the coupled movement of ions with the transport of sugars. Prewarmed solutions of bicarbonate saline containing increasing concentrations of glucose, galactose, or α-methyl glucoside were circulated through cannulated jejunal segments of pentobarbitone-anesthetized male rats. After circulating 15 min, the absorption of sugar by the gut was determined. Sugar absorption estimated by chemical methods exhibited two components: one was phlorhizin-sensitive, saturable, and generated electrical potential differences (electrogenic active component); the other was phlorhizin-insensitive, nonsaturable, and did not generate electrical potentials (diffusive component). The diffusive component of the actively transported sugars was identical to the absorption behavior of sorbose, a hexose which is not actively transferred. A method was developed for correcting the data obtained from chemical absorption studies for the diffusive component. The corrected, operational kinetic constants for apparent K_m, obtained by this method were not significantly different from values obtained electrically. The identity between the values obtained by the two methods supports the concept that they represent a measure of the same rate-limiting step in the absorption process. The electrical method for obtaining apparent K_m appears to offer a simple, relatively rapid method of obtaining major operational kinetic parameters of the active intestinal electrogenic absorption process; the technique can also be used with amino acids.

2458 URINARY EXCRETION OF 5-METHYLTETRAHYDROFOLATE AND LIVER S-ADENOSYLMETHIONINE LEVELS OF RATS FED A VITAMIN B_{12}-DEFICIENT DIET.

(E.) Vidal, A. J.; Stokstad, E. L. R. (Dep. Nutr. Sci., Univ. California, Berkeley). *Biochim. Biophys. Acta* 362(2):245-257, 1974.

The effect of ethionine and methionine on the uptake and urinary excretion of tritiated folic acid was studied, along with the effect of methionine and vitamin B_{12} on the liver concentration of S-adrenoxyl-methionine. Weanling male Sprague-Dawley rats were maintained on a basal diet deficient in vitamin B_{12} and containing only a 0.2% methionine. Supplemental D,L-methionine (15 g/kg) and vitamin B_{12} (100 μg/kg) were included in the diet, and supplemental D,L-ethionine (12.5 mg) was injected i.p. Tritiated folic acid (30 μCi) was injected i.p. and 24 hr later the folate derivatives in the liver were determined by DEAE-cellulose and sephadex chromatography. The uptake of radioactivity by the liver was depressed in the animals fed the basal diet. The uptake returned to control values when methionine, ethionine, and/or B_{12} were given as supplements; the increased uptake occurred primarily in the polyglutamate fractions. The basal diet also caused an increase in the excretion of radioactivity in the urine; in these animals, 5-methyltetrahydrofolate represented 65% of the total urinary radioactivity, while 10-formyltetrahydrofolate plus 5-formyltetrahydrofolate represented 19%. B_{12}, methionine, and/or ethionine supplementation normalized these levels to about 45% and 39%, resp. Rats fed the basal diet showed a significant decrease (to approximately 33 nM/g wet tissue) in hepatic S-adenosylmethionine. Dietary supplementation with methionine and/or B_{12} returned the levels to a normal 60 nM/g. Perfusion of the deficient liver with 300 μM of L-methionine for 1 hr increased the levels to approximately 115 nM/g. The effect of methionine appears to be direct, while that of B_{12} is mediated *via* the *de novo* synthesis of methionine. The results support the "methyl-block" hypothesis, which holds that in a primary cobalamin deficiency, folate may be trapped as N-5-methyltetrahydrofolic acid due to a partial block in the methylation of homocysteine and an essentially irreversible N-5-methyltetrahydrofolic acid reductase reaction.

2459 THE DIFFERENCE IN THE CLEARANCE OF INTERSTITIAL ALBUMIN BY THE LYMPHATICS FROM THE STOMACH AND THE SMALL AND LARGE INTESTINE.

(E.) Sheppard, M. S.; Sterns, E. E. (Dep. Surg., Queen's

Univ., Kingston, Canada). *Surg. Gynecol. Obstet.* 140(3):405-408, 1975.

The ability of the lymphatics to clear interstitial protein from the stomach, mid-portion of the small intestine, and colon was studied. Radioiodinated serum albumin (0.05 ml) was injected into the stomach, small intestine, and colon of pentobarbital-anesthetized dogs. Thoracic duct lymph was collected over the following 5 hr, and portal and vena caval blood samples were drawn intermittently during the same period; saline, equal in volume to the blood and lymph removed, was infused i.v. During the 5-hr experimental period, about 9% of the interstitially injected albumin was returned by the thoracic duct lymph; 98 min were required for 0.1% of the injected dose to appear in the lymph. Immediately after albumin injection, 1.1% of the injected dose appeared in the blood; this increased to 2.3% after 5 hr. Residual activity at the site of injection was 44%. Similar results were obtained after the injection of albumin into the colon. Significantly more of the injected activity was recovered from the thoracic duct lymph after injection into the small intestine (37%) than after injection into the stomach or colon. The time required for 0.1% of the dose to appear in the lymph (13 min) was also significantly lower after injection into the small intestine. The initial and final blood values (3.6% and 6.3%) were higher after small intestinal injection, and significantly less radioactivity remained at the site of injection (8.6%). The results suggest that the small intestine clears interstitial albumin more rapidly and effectively than the large intestine and stomach and that the colonic and gastric lymphatics behave similarly to each other and significantly differently from those of the small intestine with regard to the transport of interstitial albumin.

2460 STUDIES ON A WIDE-SPECTRUM INTESTINAL DIPEPTIDE UPTAKE SYSTEM IN THE MONKEY AND IN THE HUMAN.

(E.) Das, M.; Radhakrishnan, A. N. (Christian Med. Coll. Hosp., Vellore, India). *(Biochem. J.* 146(1):133-139, 1975.

The intestinal transport of glycine and leucine residues of glycyl-L-leucine was studied in the monkey and in the human *in vitro*. The region of the monkey intestine at 35-40% distance of the total length of intestine from the pyloric end was used in all experiments. The human intestinal specimen (7.6 cm long) was resected from the jejunal region of a patient undergoing corrective surgery for complications arising after a gastroenterostomy. Each intestinal strip (10-20 mg) was preincubated at the same temperature as the incubation step in 2 ml of oxygenated Krebs-Ringer bicarbonate buffer, containing 0.5% glucose. The medium was then aspirated, fresh medium containing the peptide solution was added, and the mixture incubated for 2 min at 37 C. Radioactivity was measured in a liquid-scintillation counter. Uptake of both [^{14}C]glycyl-L-leucine and glycyl-L-[^{14}C]-leucine showed similar K_t values, but there was a marked difference in the maximal uptake rate (V_{max}) values. This difference in the V_{max} values may be due to the greater efflux rate of glycine from the tissue. Arrhenius plots of both [^{14}C]glycyl-L-leucine uptake and glycyl-L-[^{14}C]leucine uptake in the monkey intestine showed a discontinuity at about 20 C. The activation energies above and below the discontinuity are similar for both [^{14}C]glycyl-L-leucine uptake and glycyl-L-[^{14}C]leucine uptake. These similarities suggest that the dipeptide glycyl-L-leucine is transported as one unit. In the monkey intestine, glycyl-L-leucine uptake was inhibited by a wide variety of dipeptides, including those containing acidic and basic amino acids. The inhibition was shown to be competitive by using 4 representative dipeptides: L-alanyl-L-alanine, L-alanyl-L-leucine, L-glutamyl-L-glutamic acid and L-lysyl-L-lysine. The results suggest that in the monkey intestine there may be a dipeptide uptake system with an extremely broad specificity. The specificity of glycyl-L-[^{14}C]leucine uptake in the human intestine was studied in a very limited way. All 5 dipeptides tested were inhibitory. L-Alanyl-L-leucine and L-lysyl-L-phenylalanine were strong inhibitors, whereas L-glutamyl-L-glutamic acid, glycyl-L-proline and L-prolyl-glycine were less potent inhibitors. The results suggest that the specificity of dipeptide uptake in the human may be very similar to that in the monkey.

2461 SMALL INTESTINAL MALABSORPTION OF VITAMIN B_{12} IN IRON-DEFICIENT RATS.

(E.) Yeomans, N. D.; St. John, D. J. B. (Monash Univ. Dep. Med., Melbourne, Australia). *Pathology* 7(1):35-44, 1975.

The mechanism of vitamin B_{12} malabsorption in iron deficiency was studied in female Sprague-Dawley rats. Weanling rats were maintained on an iron-deficient diet and bled at weekly intervals to speed the development of iron deficiency. Control rats were fed the iron-deficient diet supplemented with ferrous iron and some of the iron-deficient rats were repleted with parenteral iron before measurement of B_{12} absorption. B_{12} absorption was determined by isolating small intestinal loops *in vivo* and measuring the absorption of ^{57}co-vitamin B_{12} bound to a known quantity of intrinsic factor in the gastric juice. The mean corpuscular hemoglobin concentration was significantly reduced in the iron-deficient rats and no stainable iron was present in their livers. In these animals, the intestinal uptake and transport of B_{12} were significantly below control values; intestinal uptake and transport were to some extent interdependent. In the iron-deficient rats repleted with iron, the uptake and transport of B_{12} were normal within 3 days; at this time, the mean hemoglobin concentration had increased significantly and iron had reappeared in the hepatocytes and was present in Kupffer cells in supra-normal amounts. There was no correlation between hemoglobin level and B_{12} absorption, although there was a significant inverse relationship between hemoglobin level and ^{57}Co-B_{12} incorporation into the liver. Basal intrinsic factor secretion did not differ in the iron-deficient and control rats, and there was no significant difference in bacterial counts in the intestinal washings or small intestinal histology. Cecal enlargement, due primarily to increased cecal contents, was noted in all iron-deficient and none of the iron-supplemented rats. The results indicate that malabsorption of B_{12} in iron deficiency occurs as a result of an abnormality in the intestinal phase of absorption and is unrelated to any possible effect of iron deficiency on the stomach.

2462 METABOLISM OF IRON BY RATS FED WHEAT DIETS SUPPLEMENTED WITH LYSINE AND METHIONINE. *(E.)* Miller, J. (Univ. Georgia Coll. Agric. Exp. Stn., Georgia Stn., Experiment). *Nutr. Rep. Int.* 10(1):1-8, 1974.

The effect of the protein quality of bread on the absorption of iron from the bread was studied. Weanling Sprague-Dawley rats were maintained for 6 weeks on gluten (20%) or raw white wheat flour (88.8% enriched white wheat flour) diets supplemented with 0, 0.25, or 0.5% l-lysine HCl or 0.45% lysine plus 0.2% l-methionine. After 6 weeks, the animals were exsanquinated and their hematological status assessed. The animals fed the 20% gluten diet grew slowly; supplementation of the diet with lysine brought about a marked improvement in growth rate and feed efficiency which were directly related to the amount of lysine added. The rats fed the unsupplemented flour diet also gained weight slowly, but grew at a greater rate than those fed the unsupplemented gluten diet. The addition of lysine to the flour diet more than doubled the growth rate with no increase in food intake; the further addition of methionine resulted in reduced food intake with no change in growth rate. However, even with the addition of both lysine and methionine, the growth rate was only about 1/2 that expected of animals fed balanced diets. The addition of lysine to either diet increased the total iron content in the spleen and carcass, but had little effect on the iron content of the liver. The concentration of iron in the livers of the flour-fed rats was unusually high compared with rats fed a balanced diet. Amino acid supplementation of both diets increased the blood hematocrit and the blood hemoglobin concentration. In the flour-fed animals, lysine also increased the average volume/cell and the quantity of hemoglobin/cell, but lowered the serum iron content. In the gluten-fed rats, lysine increased the serum binding capacity. Osmotic fragility of the RBC was not affected by diet. The results indicated that the low protein quality of the 2 diets resulted in a relatively greater diminution in the synthesis of hemoglobin compared with other proteins associated with growth; as a result, an excessive amount of the absorbed iron was transferred to storage compartments such as the liver and bone marrow.

2463 IN VIVO D-GLUCOSE ABSORPTION IN THE DEVELOPING RAT SMALL INTESTINE. *(E.)* Younoszai, M. K.; Lynch, A. (Coll. Med., Univ. Iowa, Iowa City). *Pediatr Res* 9(3):130-133, 1975.

The rates of D-glucose absorption in the small intestine of rats of various ages were measured *in vivo* using a one-pass perfusion technique. Solutions of D-glucose (1-20 mg/ml) were perfused *in situ* through the jejunum and ileum of anesthetized Holtzman rats aged 7-8, 14-15 (suckling), 21-23 (weanling), 35-36, or 70-73 days. The amounts of glucose absorbed expressed as percentage of load perfused (normalized for intestinal weight, mg/hr/g wet weight) were greater in the weanling than in suckling pups. The rate of glucose absorption increased with increasing glucose concentration in the perfusion solutions and reached a plateau when the concentration exceeded 3 mg/ml in the suckling and 10 mg/ml in the weanling rats. Based on intestinal weight, absorption rates (mg/hr/gm wet weight) from solutions containing 10 mg/ml glucose were 2-fold higher in the 21- to 23-day-old rats than in the 7- to 8-day-old pups. Glucose absorption rates (mg/hr/g wet weight of the perfused intestine) from the 20 mg/ml solution were similar in rats aged 21-23 (64), 35-36 (60), and 70-73 (58) days; however, when based on length of intestinal segments, absorption rates were significantly greater in the older rats. The data suggest that in rats the ability of the small intestine to absorb glucose/unit weight about doubles at the time of weaning as compared with the suckling period, with no further enhancement thereafter. They further suggest that the same stimulus which increases small intestinal sucrase activity also brings about changes in the glucose transporting mechanism.

2464 EFFECT OF ASPIRIN, ANTACID, AND ALCOHOL ON THE POTENTIAL DIFFERENCE IN THE HUMAN STOMACH. *(Ger.)* Caspary, W. F. (Med. Clin., Univ. Gottingen, Germany). *Z. Gastroenterol.* 12(Suppl.): 419, 1974.

2465 THE EFFECT OF TEA ON IRON ABSORPTION. *(E.)* Disler, P. B.; Lynch, S. R.; Charlton, R. W.; Torrance, J. D.; Bothwell, T. H.; Walker, R. B.; Mayet, F. (Iron Red Cell Metab. Unit, South African Med. Res. Counc., Johannesburg). *Gut* 16(3):193-200, 1975.

MOTILITY

2501 INHIBITORY ACTIONS OF LAXATIVES ON MOTILITY AND WATER AND ELECTROLYTE TRANSPORT IN THE GASTROINTESTINAL TRACT. *(E.)* Stewart, J. J.; Gaginella, T. S.; Olsen, W. A.; Bass, P. (Cent. Health Sci., Univ. Wisconsin, Madison). *J. Pharmacol. Exp. Ther.* 192(2):458-467, 1975.

The effects of an irritant (castor oil) and an osmotic (magnesium sulfate) diuretic on gastrointestinal motility and water and electrolyte transport were compared in 6 healthy dogs. Circular smooth muscle activity was monitored by extraluminal strain gauge transducers at different sites along the gastrointestinal tract following gastric intubation of 45 ml of water and castor oil or a 30% solution of magnesium sulfate, after feeding or 20 hr fasting. Decreases in total activity were found for both cathartics in the antrum and ileum. Further analysis revealed that decreases in the ileum occurred primarily due to a decrease in contractile rate, whereas antral decreases could be attributed primarily to a decrease in force/contraction. Proximal colonic activity tended to decrease after laxatives and feeding. The effects of ricinoleic acid, isotonic and hypertonic solutions of magnesium sulfate and mannitol on net water and electrolyte absorption were tested on everted segments of hamster jejunum. Sodium ricinoleate (2.0 mM) reduced net water transport by 48%. Magnesium sulfate, like mannitol, only reduced net water absorption when present as a component of a hypertonic mucosal solution. The results suggest that both inhibition of water absorption and reduced circular smooth muscle activity may be important factors in castor oil- and magnesium sulfate-induced catharsis.

2502 THE VOLUME AND ENERGY CONTENT OF MEALS AS DETERMINANTS OF GASTRIC EMPTYING. *(E.)*

Hunt, J. N.; Stubbs, D. F. (Guy's Hosp. Med. Sch., London, England). *J. Physiol. (Lond.)* 245(1):209-225, 1975.

Information from 33 published and unpublished studies of gastric emptying was used to determine quantitative relations between nutritive density of meals and emptying behavior of the stomach. Calculations were based upon gastric emptying of food during the first 60 min of the emptying process, volumes of meals 50-1250 ml, and varied composition with nutritive densities of 0-2.3 kcal/ml. The greater the density of the meal, the lesser was the volume transferred to the duodenum (independent of initial volume), but the rate of delivery of energy to the duodenum (nutritive density times volume delivered) was not affected. Based upon the interaction of stimulus (kcal/ml) and duodenal receptors it was possible to predict the rate of gastric emptying, given the nutritive density of the meal. Dietary carbohydrates and triglycerides added to test meals slowed gastric emptying (higher concentration, slower emptying) due to intraduodenal concentration of digestion products (monosaccharides or salts of fatty acids). It is concluded that isocaloric amounts of fat, protein and carbohydrate (e.g. 4 g fat, 9 g carbohydrate) result in equal slowing of gastric emptying.

2503 RATE OF GASTRIC EMPTYING OF PHENOL RED IN A RABBIT. *(E.)*

Goto, S.; Yamagata, T.; Tsuzuki, O.; Iguchi, S. (Fac. Pharm. Sci., Okayama Univ., Japan). *Chem. Pharm. Bull. (Tokyo)* 21(11): 2495-2499, 1974.

The gastric emptying of phenol red both alone and with the simultaneous administration of aminopyrine and caffeine was studied quantitatively in male rabbits. After a series of 5 washings of the rabbit stomach with warm water *via* a vinyl tube, 100 ml isotonic solution containing phenol red alone or phenol red and one of the drugs was instilled into the stomach during 1 min. The vinyl tube was removed and reinserted after a specified time for removal of the gastric content by gentle aspiration with a syringe. Twelve rabbits were used in the experiment with phenol red alone; the tests were performed at weekly intervals with the same rabbit. For the first 2 months the gastric emptying behavior was almost always reproducible, but there was some variation after 3 months. The gastric emptying pattern, 75 min after p.o. administration, showed the percent of residual phenol red in the rabbits at the initiation of the experiment to range from 16.5 to 25.5%, whereas after 3 months the range of values was 4.1 to 7.0%. Corresponding ranges for the residual total volume were 33 to 41 ml and 13 to 16 ml, resp. Gastric emptying and the volume of gastric content were governed by first-order kinetics in the case of phenol red alone. The simultaneous administration of aminopyrine (900 mg) caused a smaller exponential decline in the amount of phenol red than was found when phenol red was administered alone. Caffeine (50, 200, and 300 mg) produced no such effect. These results support the previously reported hypothesis that aminopyrine suppresses the transfer of phenol red to the duodenum and that simultaneously administered drugs such as caffeine, which have no effect on the gastric emptying of phenol red, can eliminate the effect of aminopyrine and reduce its gastric emptying time.

2504 INTESTINAL SMOOTH MUSCLE ELECTRICAL POTENTIALS RECORDED FROM SURFACE ELECTRODES. *(E.)*

Brown, B. H.; Smallwood, R. H.; Duthie, H. L.; Stoddard, C. J. (Weston Park Hosp., Sheffield, England). *Med. Biol. Eng.* 13(3):97-103, 1975.

The source of electrical signals recorded from the human small intestine using surface electrodes was studied. Electrodes were placed on the trunks of 16 normal subjects, 3 pairs over the gastroduodenal area and a 4th pair placed across the chest and used to record respiration. Recordings were made after fasting and immediately following a meal. Fourier analysis and correlation methods were used to analyze the data. A significant frequency component at approximately 3 cycles/min (average 3.02 min) was found in 88% of the stretches of record analyzed. It is unlikely that the signals were an electrode artifact or that they were the result of mechanical artifacts from the gut. Evidence indicates that the signal arose from the basic electrical rhythm of the stomach. In 28% of the recordings, consistent activity was found at a frequency of 10-12 cycles/min (average 10.8 cycles/min); this activity was found almost exclusively in the records made in the fasting state. Although this activity is near respiratory frequencies, simultaneous monitoring of respiration enabled the waveforms to be separated. The source of these rhythms is probably either the small or large bowel.

2505 INFLUENCE OF THE HORMONE ANALOGUE 13-NLE-MOTILIN AND OF 1-METHYL-3-ISOBUTYLXANTHINE

ON TONE AND CYCLIC 3'5'-AMP CONTENT OF ANTRAL AND DUODENAL MUSCLES IN THE RABBIT. *(E.)* Schubert, E.; Mitznegg, P.; Strunz, U.; Domschke, W.; Domschke, S.; Wunsch, E.; Jaeger, E.; Demling, L.; Heim, F. (Dep. Pharmacol., Univ. Erlangen-Nuremberg, Erlangen, Germany). *Life Sci.* 16(2):263-272, 1975.

To investigate whether changes in the cyclic AMP content lead to changes in smooth muscle tone and whether tone enhancement by acetylcholine and 13-norleucine-motilin is antagonized by an increase in endogenous cyclic AMP, the influence of 1-methyl-3-isobutylxanthine (isobutyltheophylline), norleucine-motilin, and acetylcholine on muscle tone and the content of cyclic AMP was studied. The cyclic AMP content of mucosa-free preparations of rabbit antral and duodenal muscles was increased 72% and 126%, resp., by isobutyltheophylline (2-3 x 10^{-4} M). 13-Norleucine-motilin (1.8 x 10^{-7} M), an analogue of the duodenal tissue hormone motilin, and acetylcholine (1.8 x 10^{-6} M) had no effect on the cyclic AMP content of the antral and duodenal muscles when given alone or in combination with isobutyltheophylline. In contrast, norleucine-motilin (1.8 x 10^{-7}) increased and isobutyltheophylline (3 x 10^{-4} M) decreased smooth muscle tone in the duodenum. The tone-enhancing effect of norleucine-motilin was reversed by the subsequent administration of isobutyltheophylline, whereas the muscle tone lowered by isobutyltheophylline was returned to its initial state by norleucine-motilin. The basic tone of the antral muscle was not reduced by isobutyltheophylline. However, pretreatment with isobutyltheophylline (2 x 10^{-4} M) significantly reduced (60%) the contraction-promoting effect of norleucine-motilin. It is assumed that changes in the tone or response of antral and duodenal muscles to norleucine-motilin administered after isobutyltheophylline are due to the increased tissue content of cyclic AMP. The antagonistic effects of cyclic AMP and motilin on the gastrointestinal muscles might be of physiological importance for the regulation of gastrointestinal motor activity.

2506 MANOMETRIC EVALUATION OF THE PAPILLA OF VATER. *(E.)* Nebel, O. T. (Nav. Reg. Med. Cent., San Diego, Calif.). *Gastrointest. Endosc.* 21 (3):126-128, 1975.

A new technique for manometry of the sphincter of Oddi is described. Preliminary studies were performed in five volunteers, and subsequent studies in 20 patients being evaluated for abdominal pain who were found to have no organic disease. The manometric catheter was 1.5 mm in diameter, 200 cm long, and the end of the tube was sealed, with a side hole 0.8 mm in diameter just behind the sealed portion. The proximal end had a standard i.v. fitting. During the measurements, the catheter was perfused with distilled water at 0.2 ml/min. Intraluminal pressure was transmitted through the catheter to an external transducer and recorded. Pressure for each min of measurement was calculated using duodenal pressure as zero reference. The catheter was inserted beyond the sphincter into the pancreatic duct or biliary tree, and slowly pulled through into the duodenum under direct endoscopic vision. Tests on the 5 volunteers demonstrated that the sedative diazepam (15 mg i.v.) caused no significant change in sphincter pressure, and this dose was used to sedate the 20 patients. Sphincter pressure in the 20 patients ranged from 18-45 mm Hg. The procedure was well tolerated by the patients and added only 15 min to normal duodenoscopy time. It is concluded that there is a high pressure area in the region of the papilla of Vater that can be measured by endoscopic manometric techniques.

2507 RESPONSE OF THE HUMAN CARDIAC SPHINCTER TO CIRCULATING PROSTAGLANDINS $F_{2\alpha}$ AND E_2 AND TO ANTI-INFLAMMATORY DRUGS. *(E.)* Dilawari, J. B.; Newman, A.; Poleo, J.; Misiewicz, J. J. (Cent. Middlesex Hosp., London, England). *Gut* 16(2):137-143, 1975.

The effects of i.v. prostaglandins $F_{2\alpha}$ and E_2 on motor responses of the gastroesophageal junction, and the effect of rectal indomethacin on cardiac sphincter pressure, were studied in 41 subjects. Three of the 41 were normal while 37 had upper abdominal complaints related to peptic ulceration or gastroesophageal reflux. Bolus injection of prostaglandin $F_{2\alpha}$ (2.5-40 μg/kg) had no effect on cardiac sphincter pressure, but i.v. infusion (0.05-0.8 μg/kg/min) for 20 min resulted in a marked increase of sphincter pressure from 10 min after the start to 15-20 min after the finish of infusion. Sphincteric relaxation during swallowing was prolonged, and this effect was significant in 4 subjects given 0.8 μg/kg/min. Neither esophageal peristalsis nor gastric fundic motility was significantly affected by prostaglandin $F_{2\alpha}$; plasma gastrin levels were unaltered. Although prostaglandin E_2 (0.1-0.08 μg/kg/min) had no effect on any variable of intraluminal pressure, i.v. infusion of 0.08 μg/kg/min inhibited sphincter contractions to serial bolus i.v. injections of pentagastrin (0.1 or 0.2 μg/kg) in 2 of 3 subjects. Rectal indomethacin (200 mg) resulted in a slow rise of cardiac sphincter pressure, suggesting that endogenous synthesis of an inhibitory (E-type) prostaglandin was suppressed. These results indicate that prostaglandin E_2 may be concerned in the regulation of cardiac sphincter tone in man, and that prostaglandin $F_{2\alpha}$ may be useful in the treatment of gastroesophageal reflux.

2508 DIETARY ORIGIN OF CIRCADIAN VARIATIONS IN THE ELECTRICAL ACTIVITY OF THE SMALL INTESTINE IN THE RAT. *(Fr.)* Ruckebusch, M.; Ferre, J. P. (Natl. Vet. Sch., Toulouse, France). *C. R. Soc. Biol.* (Paris) 167(12):2005-2009, 1974.

Jejunal electromyograms of Wistar rats show slow waves (frequency 30-36/min); 45% of these are followed by salvos of 3 to 20 potentials having amplitudes of 50-200 μV in rats fed *ad libitum.* The salvos may either occur very irregularly or in a segmentary manner after every slow wave for 2-3 min.

This type of activity is propagated at a rate of about 2 cm/min along the small intestine. Electrodes were placed at 4 cm intervals along the small intestine of Wistar rats, and the jejunal electromyogram was recorded. There were four groups of 10 rats each: 1) controls fed *ad libitum*; 2) those subjected to fasting with precautions taken to prevent coprophagy; 3) those subjected to fasting with no precautions taken to prevent coprophagy; and 4) those subjected to fasting and equipped with a gastric fistula. In group 1, about 60% of the slow waves were followed by irregular salvos during feeding. When rats stopped eating, about 30% of the slow waves were followed by segmentary salvos. In group 2, salvos followed about 30% of the slow waves and were segmentary after 5 to 6 hr of fasting. Irregular salvos persisted during part of the first 24 hr in group 3. In group 4, when the fistula was used to keep the stomach empty, the pattern of intestinal motility did not change significantly in fasting animals; there were two to three phases of segmentary salvos/hr. When the stomachs of these rats were filled through the fistula, segmentary activity disappeared and was replaced by irregular activity over a period of 3 - 6 hr. Thus, the presence of segmentary salvos in the rat depends upon whether the stomach is empty or full.

2509 INVESTIGATION OF SMALL BOWEL TRANSIT TIME IN MAN UTILIZING PULMONARY HYDROGEN (H_2) MEASUREMENTS. *(E.)* Bond, J. H. Jr.; Levitt, M. D.; Prentiss, R. (VA Hosp., Minneapolis, Minn.). *J. Lab. Clin. Med.* 85(4):546-555, 1975.

A new method of determining small bowel transit time, using lactulose as a test substance and pulmonary hydrogen as an indicator, was investigated. Studies were performed in 42 healthy subjects after a 12-hr fast. Isotonic lactulose solution was ingested (5, 10, or 20 g in 50, 100, or 200 ml water, resp.), and pulmonary hydrogen excretion was measured by having the subjects breathe into a closed system from which periodic aliquots were removed at 8-min intervals and analyzed by gas chromatography. Simultaneously, polyethylene glycol transit time to the terminal ileum was measured in 7 of the normal subjects plus two patients who had had partial gastric resections with Billroth II anastomoses. These subjects were intubated with a mercury-weighted 1.6-mm diameter tube with the tip in the distal ileum. Tube length varied from 275-330 cm. Lactulose (10-20 g) and polyethylene glycol (2-3 g) were ingested, hydrogen excretion was monitered, and serial samples of terminal ileal contents were aspirated every 10 min and analyzed for polyethylene glycol content. Transit time measured by the excretion hydrogen correlated closely with the simultaneously determined time for polyethylene glycol to reach the distal ileum, but lagged behind it for an average of 7.6 min. Transit time following ingestion of 10 g lactulose in 40 subjects averaged 72 min. Repeat measurements performed in 6 subjects showed good reproducibility, differing from the original measurement by ± 14%. In 9 subjects, ingestion of 5, 10, and 20g lactulose resulted in transit times of 128, 94, and 40 min, resp. It is concluded that this technique is a valid and safe means of determining intestinal transit time in man.

2510 RELATIONSHIP BETWEEN SERUM GASTRIN CONCENTRATION AND LOWER-ESOPHAGEAL SPHINCTER PRESSURE. *(E.)* Dodds, W. J.; Hogan, W. J.; Miller, W. N.; Barreras, R. F.; Arndorfer, R. C.; Stef, J. J. (Med. Coll. Wisconsin, Milwaukee). *Am. J. Dig. Dis.* 20(3): 201-207, 1975.

The relation between lower esophageal sphincter pressure and serum gastrin was studied in 16 healthy volunteers (aged 18-30 yr). Subjects fasted overnight and esophageal manometry was performed with a 5-lumen manometric assembly. Side hole recording devices were cut out at the same axial level in 4 cases so that they were radially oriented at 90 degree angles and used to record sphincter resting pressure. A 5th recording orifice was 5 cm proximal to the others. During pressure recording, each catheter was infused with water at 1.6 ml/min. The catheter assembly was passed into the stomach and the pressure recorded by both the conventional station pull-through method, requiring several min, and a rapid pull-through method with continuous withdrawal at 0.5-1.0 cm/sec., three or more of each performed in alternating sequence. Pressure from the standard method recordings was determined by subtracting mean gastric pressure from the highest mean pressure at any station, while maximal pressure from the rapid method recordings was determined by subtracting the steady state gastric pressure during breathholding from the sphincter pressure profile peak. Immediately following the pull-throughs, a venous blood sample was drawn and serum gastrin was determined. No direct correlation was found between gastrin level and lower esophageal sphincter pressure measured by either technique. A significant inverse correlation was found in 10 of the subjects who then participated in a second study 2-8 weeks later, but in the second study the inverse correlation was not significant. Four subjects were studied a 3rd time several weeks after the 2nd study, but no direct correlations were found. It is concluded that there is no simple direct relation in man between resting lower-esophageal sphincter pressure and circulating gastrin levels.

2511 DIFFERENTIATION BETWEEN THE BIOLOGICAL ACTIVITY OF ELEDOISIN AND SUBSTANCE P ANALOGS WITH REGARD TO THEIR AFFINITY TO AND ACTIVITY ON GUINEA PIG ILEUM AND COMPARISON WITH THEIR ACTIVITY ON RAT COLON. *(Ger.)* Bergmann, J.; Oehme, P.; Beinert, M.; Niedrich, H. (Cent. Inst. Mol. Biol., Berlin-Friedrichsfelde, Germany). *Experentia* 30(11):1315-1317, 1974.

SECRETION AND METABOLISM

2517 THE ROLE OF CALCIUM AND CYCLIC NUCLEOTIDES IN α-AMYLASE RELEASE FROM SLICES OF RAT PAROTID: STUDIES WITH THE DIVALENT CATION IONOPHORE A-23187. *(E.)* Butcher, F. R. (Div. Biol. Med. Sci., Brown Univ., Providence, R.I.). *Metabolism* 24(3): 409-418, 1975.

The role of calcium and cyclic nucleotides in the *in vitro* release of α-amylase from tissue slices of rat parotid was studied using the ionophore A-23187, which transports Ca^{++} and other divalent cations across biologic membranes in the direction of the respective cation concentration gradient. Parotid glands from 7-9-week-old female Sprague-Dawley rats were sliced and incubated in media containing A-23187 dissolved in dimethylsulfoxide. α-Amylase release and tissue cyclic nucleotide levels were measured in the presence and absence of theophylline and various blocking agents. A-23187 caused a release of α-amylase from the parotid slices. This release was not affected by the addition of 1-propranolol, phentolamine, or atropine to the incubation medium, although all of these agents blocked the effects of isoproterenol, phenylephrine, and carbamylcholine on parotid slices. The ionophore also inhibited the stimulatory effect of isoproterenol on the cyclic AMP levels in the tissue slices, but only if the slices were incubated with A-23187 for 10 min before the isoproterenol was added. A-23187 increased cyclic GMP levels in the slices after 10 min incubation; in the presence of theophylline, this elevation occurred after 5 min incubation. Both the stimulatory effect on α-amylase release and the increase in cyclic GMP by A-23187 were dependent on the presence of Ca^{++} in the incubation buffer. Although these results do not define the mechanism of Ca^{++} action in stimulus-secretion coupling, they do emphasize the importance of Ca^{++} in the regulation of cyclic nucleotide levels.

SECRETION AND METABOLISM

Stomach

2525 EFFECT OF SECRETIN ON THE SECRETION OF ACID AND PEPSIN BY THE TOTALLY ISOLATED CANINE STOMACH. *(E.)* Kowalewski, K.; Kolodej, A. (Surg. Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Pharmacology* 12(1):57-63, 1974.

Totally isolated whole canine stomachs, perfused *ex vivo* with homologous blood, were used for study of the action of secretin on gastric secretion of acid and pepsin. During 8 hr of perfusion, stomachs were stimulated by constant infusion of 32 µg/hr of pentagastrin into gastric arteries of isolated organs. When base line secretion was established (after 3.5 hr), secretin, (60 U/hr) was also infused for 90 min into the gastric artery. Secretin injection was then interrupted, but pentagastrin infusion continued until the termination of the experiment. Secretin produced decreases of 60%, 74% and 36% in gastric secretory volume, acid output and acid concentration, resp., while stimulating pepsin output and concentration by 236% and 800%, resp. The maximal effect was seen after 30-60 min and persisted for 1-3 hr after secretin was discontinued. The dissociation of the effects of secretin on gastric acid and pepsin secretion in this system resembles the action of secretin on gastric secretion reported by others in various *in vivo* experiments.

2526 HISTAMINE RELEASE BY GASTRIC STIMULANTS. *(E.)* Rangachari, P. K. (Univ. California Sch. Med., San Francisco). *Nature* 253(5486):53-54, 1975.

The rates of histamine and acid release in response to pentagastrin, acetylcholine and dibutyryl cyclic AMP (cAMP) were studied in the isolated gastric mucosa of the bullfrog, *Rana catesbeiana*. Acid secretion from freshly mounted mucosa ranged from 6-10 µEq/hr but declined to resting levels of $\leq$ 2 µEq/hr over an 8-12 hr period, in spite of nutrient solution replenishment. Histamine release as determined by fluorometric analysis, decreased over the same period from about 500 ng/hr to a resting level of about 140 ng/hr. Addition of pentagastrin (5×10^{-6}M) or acetylcholine (10^{-3}M) to resting mucosa produced a 2-fold increase in the rates of both histamine and acid release, the peak of histamine release (15 min) preceeding that of acid secretion (25-30 min). Dibutyryl cAMP (5mM) produced a 5-fold increase in acid secretion but had no effect on histamine release. Acid secretion of resting mucosa was also stimulated by addition of nutrient solution incubated for 90 min with actively secreting mucosa. It is thus concluded that histamine released by frog gastric mucosa is responsible for stimulating acid secretion *in vitro* and that histamine is the common mediator for acetylcholine and pentagastrin in this system.

2527 EFFECT OF HISTAMINE ON IMMUNOREACTIVE GASTRIN IN GASTRIC JUICE AND IN SERUM. *(E.)* Stadil, F.; Malmstrom, J.; Miyata, M; Rehfeld, J. F. (Righosp., Copenhagen, Denmark). *Surgery* 77(3):345-350, 1975.

Gastric juices from 82 patients with various dyspeptic disorders were analyzed by radioimmunoassay for gastrin following histamine injection (0.04 mg/kg s.c.). Preliminary *in vitro* studies showed that gastrin added to untreated gastric juice decreased rapidly from 135 pg/ml to less than 10 pg/ml in less than 1 min. This could be prevented by boiling or neutralizing the gastric juice. None or only a trace amount of gastrin was found in untreated, boiled, or boiled and neutralized gastric juice in every patient, including 3 patients with achlorhydria. Histamine injection (0.04 mg/kg s.c.) did not influence this and was without effect upon serum gastrin concentrations of 9 duodenal ulcer patients. Because gastrin apparently is degraded rapidly by gastric juice, this study does not necessarily disprove that gastrin is secreted into the stomach. However, the virtual absence of gastrin in all specimens examined, including some collected directly upon boiling water bath during continuous gastric aspiration, lends no support to this speculation. Because gastrin does not survive even a short exposure to gastric juice without degradation, it is suggested that earlier reports on the presence of gastrin within the stomach are questionable.

2528 THE EFFECT OF OPTIMUM THERAPEUTIC DOSE OF POLDINE ON ACID SECRETION, GASTRIC ACIDITY, GASTRIC EMPTYING, AND SERUM GASTRIN CONCENTRATION AFTER A PROTEIN MEAL. *(E.)* Bieberdorf, F. A.; Walsh, J. H.; Fordtran, J. S. (Univ. Texas Southwest. Med. Sch., Dallas). *Gastroenterology* 68(1):50-57, 1975.

The effects of the optimum therapeutic dose of poldine on gastric function was studied in 5 normal volunteers. Five oz. of steak and a slice of toast and butter were homogenized, the pH set at 5.0, and infused into the stomach through a Levin tube. Acid secretion rate was measured for 3 hr after the meal by *in vivo* titration with $NaHCO_3$. To measure gastric pH and acidity, pH was measured by pH meter on a separate day. On a 3rd day of experiment, 5 g polyethylene glycol in 25 cc water were infused into the stomach 90 min after the meal. Stomach contents were then mixed and aspirated, and the stomach rinsed with saline and again aspirated, and the gastric volume and buffer content calculated. All experiments were done both with and without poldine. Poldine reduced acid secretion by 25-40% from 1 hr after the start of the experiment. Gastric acidity after poldine was reduced from 15% at 90 min to 50% after 180 min. Gastric volume and buffer content at 90 min were calculated to be 370 ml and 21 mEq, resp. It is concluded that the inhibition of gastric acidity by poldine is due to reduced secretion rather than to delayed emptying of food buffer.

2529 DEPLETION OF ANTRAL GASTRIN AFTER FOOD IN RATS. *(E.)* Reeder, D. D.; Watayou, T.;

Booth, R. A. D.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Am. J. Surg.* 129(1):67-70, 1975.

The effect of feeding on tissue gastrin values was studied in rat fundus, antrum and proximal small intestine. Sprague-Dawley rats (80) were fasted for 48 hr, fed, and in groups of 10 decapitated at 5, 10, 15, 20, 25, 30, and 40 min after feeding. Ten non-fed rats served as controls. Blood was immediately taken from the neck for radioimmunoassay, and the stomach, duodenum, proximal 5 cm of the jejunum and a specimen of the rectus abdominus muscle were removed. Serum gastrin concentrations in all fed rats were significantly higher than control values (269 pg/ml after 25 min and 160 pg/ml, resp.). Serum gastrin concentrations in the antrum were significantly less than control values (2690 ng/g at 5 min and 3850 ng/g at 15 min *versus* 6900 ng/g in fasting controls). Total gastrin content dropped from 1289 ng to 647 ng at 5 min, and to 428 ng at 30 min. In the gastric fundus the concentration increased from 9.7 to 21.8 ng/g in 40 min. Gastrin content increased from 12.5 to 28.1 ng. In the duodenum, gastrin-like immunoreactivity concentration rose from 77.2 to 260 ng/g after 25 min. Content rose significantly from a control value of 99.4 ng. It is concluded that in rats, feeding causes an abrupt increase in serum gastrin persisting for at least 40 min, that the fundus is a target organ, and the duodenum probably synthesizes gastrin. The antrum results suggest that early gastrin release may trigger a mechanism for synthesis that reacts cyclically with the release.

2530 ROLE OF BILE ACIDS IN THE PATHOGENESIS OF ASPIRIN-INDUCED GASTRIC MUCOSAL HEMORRHAGE IN RATS.

(E.) Semple, P. F.; Russell, R. I. (R. Infirm., Glasgow, Scotland). *Gastroenterology* 68 (1):67-70, 1975.

The effect of combined aspirin and bile acids on gastric mucosal hemorrhage was studied in the rat. Sprague-Dawley rats were fasted 24 hr and fed acetylsalicylic acid in a 1% suspension of carboxymethylcellulose to which was added in different cases 5 mM of various bile acids in glucose saline. Controls were given equal parts of the acetysalicylic acid suspension and the glucose saline. All administered solutions had a pH of 4.5. The rats were killed 4 hr after administration and the stomachs removed and examined for hemorrhage. A dose of 64 mg/kg of acetylsalicylic acid was found to cause lesions in 32% of the rats, and this dose was then used in conjunction with taurocholic, taurodeoxycholic, glycholic, cholic, deoxycholic, or chenodeoxycholic acids. Significant findings were lesions in 82.4% of the rats treated with taurocholic acid, 64.3% with taurodeoxycholic acid, and 64.3% with glycholic acid. Bile acids used without acetylsalicylic acid had no effect. It is concluded that certain bile acids reduce the threshold for aspirin-induced gastric mucosal damage in the rat.

2531 THE EFFECT OF VAGAL STIMULATION ON GASTRIN RELEASE AND ACID SECRETION.

(E.) Maher, J. W.; Wickbom, G.; Woodward, E. R.; McGuigan, J. E.; Dragstedt, L. R. (Coll. Med., Univ. Florida, Gainesville). *Surgery* 77(2):255-260, 1975.

Serum gastrin response to vagal stimulation was studied in 8 mongrel dogs with gastrointestinal continuity. Each dog was given a chronic esophageal fistula and a vagally-denervated fundic pouch. Six were later given an isolated vagally-innervated antral pouch and a gastroduodenostomy to reestablish continuity. Before and after the creation of the antral pouch the dogs were sham fed 500 g horsemeat after a 20 hr fast. The meal was constantly removed through the esophageal fistula and recycled for 30 min. Gastric juice was collected from the fundic pouches every 15 min for 1 hr before and 3 hr after each sham feeding, and the acid output determined. Blood for serum gastrin determination by radioimmunoassay was drawn just before sham feeding and hourly afterwards until the acid output returned to basal level. Preoperative sham feeding caused a gastric acid increase from 32-322 μEq/15 min and of serum gastrin from 32-43 pg/ml (the latter not statistically significant). After the antral pouches had been created, the basal serum gastrin level was unchanged but sham feeding caused a rise to 177 pg/ml which decreased to 89 pg/ml after 1 hr and 51 pg/ml by 3 hr. There was no significant change in the acid output. It is concluded that vagal gastrin release in sham fed dogs with gastrointestinal continuity is small or insignificant, and direct vagal stimulation of the parietal cells is the major mechanism in sham feeding-induced acid secretion.

2532 GASTRIN CELL HYPERPLASIA IN RATS WITH CHRONIC ANTRAL STIMULATION.

(E.) Lehy, T.; Voillemot, N.; Dubrasquet, M.; Dufougeray, F. (INSERM, Beaujon Hosp., Clichy, France). *Gastroenterology* 68(1):71-82, 1975.

Topographic distribution of antral gastrin cells was studied in rats with antrocolic transpositions to verify whether colonic conditions could modify gastrin and other endocrine cell populations after acid feedback suppression. Wistar rats (9 males) were surgically prepared with transposition of total gastric antrum onto the colon, and provided with a gastric fistula in the rumen; 9 controls were given only the fistula. All were fasted for 18 hr. A blood sample was taken for radioimmunoassay and a 2 hr basal gastric secretory study was performed. The rats were killed 15 days after surgery, and the entire stomach and the antrum with its adjacent colon were fixed in Bouin's fluid. The specimens were cut into strips and adjacent sections studied by immunofluorescence and argyrophilic techniques, and by electron microscopy. The acid output of the operated rats (489 μEq/2 hr) showed a significant increase over that of the controls (130 μEq/2 hr), and gastrinemia was also significantly elevated (171 pg/ml for operated; 20 pg/ml for controls). In the operated rats, gastrin cells were found to be significantly more numerous than in the controls except in the strip closest to the pylorus. Values increased from 4.3 to 6.7 (esophagus to pylorus) in controls and remained between 7.1 and 7.2 in operated rats, dropping to 6.7 in the last strip nearest the ligation. The argyrophil cell count increased slightly toward the esophageal junction and decreased significantly in the middle 3rd of all strips, but mean counts were higher than those of controls. There was a 78% increase in gastrin cells/glandular tube, but the gastrin:argyrophil ratio was similar in both operated and control rats. Electron micrography also showed an increase in the number of all endocrine cells in the tubes. It is concluded that antrocolic transposition results in increases in density of both argyrophil and gastrin cells after 15 days.

2533 ABERRATIONS IN HOLLANDER TEST RESPONSE AFTER INCOMPLETE VAGOTOMY. COMPENSATING EFFECT OF ANTRAL RESECTION IN THE DOG. *(E.)* Vogel, S. B.; Orahood, R. C.; Eisenberg, M. M. (Dep. Surg., Univ. Minnesota, Minneapolis). *Am. J. Surg.* 129(1): 55-61, 1975.

The role of antral gastrin was evaluated in the response to Hollander vagal stimulation after partial vagotomy with either pyloroplasty or antrectomy. Fourteen mongrel dogs were given gastric fistulas and fasted 18 hr prior to experimental procedures. Response to vagal stimulus by i.v. insulin (0.2 U/kg) or 2-deoxy-D-glucose (200 mg/kg) or parietal cell stimulation by histamine infusion (0.16 mg/kg/hr) were tested. Gastric juice samples were collected every 30 min and the acidity determined. During vagal stimulation, venous blood samples were collected every 15 min for 1 hr and every 30 min subsequently. After control measurements were made, the dogs were given either an anterior vagectomy and pyloroplasty, or an anterior vagectomy and a Billroth I pylorus-preserving antrectomy, and the experiments were repeated. In the group given the pyloroplasty, there was a 19% reduction in acid response to both insulin and 2-deoxy-D-glucose from control values (12.05 and 13.18, resp.). The serum gastrin concentration was uniformly elevated over control values, but not to a significant degree. In the antrectomized group the peak acid outputs were 0.51 and 3.68 mEq after insulin and 2-deoxy-D-glucose, resp., representing reduction from control values of 96 and 67%, resp. Surgery had no apparent effect on histamine-induced acid secretion. It is concluded that the Hollander test may be inaccurate and misleading in vagotomy assessment in antrectomized patients.

2534 INFLUENCE OF PANCREATIC SECRETION ON GASTRIC SECRETION IN DOGS. *(E.)* Palasciano, G.; Tiscornia, O.; Dzieniszewski, J.; Sarles, H.; Vincent, J. P.; Lazdunski, M. (Dig. Pathol. Res. Unit, INSERM, Univ. Nice, France). *Digestion* 11(1/2):64-71, 1974.

The influence of pancreatic secretion on gastrin-stimulated gastric secretion was studied in dogs. Seven dogs were prepared with chronic gastric and duodenal fistulas; gastrin (6 μg/kg/hr) was continuously infused at a constant rate *via* a polyethylene catheter inserted into a leg vein. Pancreatic juice was collected and stored; gastric juice was collected after each 15 min period. When the plateau level of gastric secretion was reached (45-60 min), solutions of test material were infused into the second part of the duodenum and each successive 15 min period value was compared to the plateau level values of gastric secretion. Gastric secretion was significantly decreased after the administration of lyophilized pig pancreas (62%), pancreatic juice (57%), and bovine trypsinogen (33%). Intraduodenal administration of isotonic saline solution, lyophilized pig meat, trypsin, and chymotrypsinogen failed to decrease gastric secretion. The results indicate that exocrine pancreatic secretion decreases gastric secretion in dogs, and that the alkaline and protein components of the pancreatic secretion play a role in the duodenal regulation of pH; the alkaline component neutralizes the H^+ in the duodenum, and the protein component acts by means of the activation peptide of trypsinogen.

2535 INCREASED HISTIDINE AND DOPA DECARBOXYLASE ACTIVITY IN THE RAT STOMACH DURING RESTRAINT ULCER FORMATION. *(E.)* Schauer, A.; Kunze, E.; Feifel, G.; Permanetter, W.; Fraps, P. (Inst. Pathol., Univ. Munich, Germany). *Digestion* 11(1/2):12-24, 1974.

The activities of histidine decarboxylase and dopa decarboxylase (which produce the vasoactive histamine and dopamine) were determined radiometrically to investigate their possible relation with the development of gastric mucosal erosions in rats. Restraint stress was induced in 250 Wistar rats by enclosing their bodies in plaster casts. At 2 hr intervals for 3-30 hr, the stomachs were removed and the number, position, and diameter of mucosal erosions were determined; the glandular portions were minced, homogenized, and analyzed for both amino acid decarboxylases by a micromethod measuring liberated $^{14}CO_2$ radiometrically. In another series of restrained rats, histological examinations were done on sections of the glandular part of the stomach. On gross examination, erosions (almost exclusively in glandular part of stomach) were seen in 40% of the animals after 3 hr stress; the figure subsequently rose to 100% with increased duration of restraint. After 3 hr, the histidine decarboxylase showed a continuous increase in activity and attained a maximum of more than twice the control activity between 9 and 11 hr. The dopa decarboxylase activity was moderately raised until 11-13 hr after the beginning of immobilization and showed twice the activity after 13-15 hr. The activity of both amino acid decarboxylases decreased to below the normal level after 21 hr. The localization of histamine in the glandular portion of the stomach provided further argument for its participation in the formation of stress-induced erosions; the highest activity of histidine decarboxylase was also found in that area. Interpretation of the increase of dopa decarboxylase is speculative, and the need for further investigation is stressed.

2536 EFFECT OF NICOTINE HYDROGEN TARTRATE ON GASTRIC SECRETION OF NORMAL AND VAGOTOMIZED

RATS STIMULATED WITH HISTAMINE PENTAGASTRIN AND BETHANECHOL CHLORIDE. *(E.)* Kowalewski, K. (Surg.-Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Digestion* 10(6):393-401, 1974.

Wistar rats with permanent gastric fistulas, some of which had been vagotomized, were given acute and chronic infusions of nicotine to determine its effect on 24-hr output of HCl and pepsin. Secretion was stimulated by constant i.v. infusion of histamine, pentagastrin, or bethanechol chloride. Nicotine hydrogen tartrate was used in acute and chronic experiments. An i.v. infusion (240 μg/kg) for 24 hr with simultaneous collection of gastric juice demonstrated the inhibitory action of this drug on basal secretion and secretion stimulated with histamine (100 mg/kg), pentagastrin (768 μg/kg), and bethanechol chloride (2.5 mg/kg). Inhibition affected the output of HCl and pepsin, also the concentration of HCl. In nonstimulated and in bethanechol-stimulated rats, nicotine hydrogen tartrate also decreased the concentration of pepsin. Chronic treatment (given s.c.) induced the inhibition of gastric secretion under various stimulation conditions. The vagotomy-induced decrease in response to the stimulants was further reduced when nicotine hydrogen tartrate was added to the stimulants. The authors suggest the possibilities that nicotine hydrogen tartrate may directly affect chief cells of gastric glands in rats or alter the responsiveness of the cells to humoral and cholinergic stimulants.

2537 INFLUENCE OF THE PROXIMAL SMALL INTESTINE ON THE GASTRIC HYPERSECRETION IN PYLORUS-LIGATED RATS. *(E.)* Okabe, S.; Takeuchi, K.; Nakamura, K.; Takagi, K. (Fac. Pharm. Sci., Univ. Tokyo, Japan). *Am. J. Dig. Dis.* 20(2):138-147, 1975.

The mechanism of gastric-secretory inhibition caused by the simultaneous ligation of upper and lower duodenum, jejunum, or bile duct was studied in pylorus-ligated Donryu rats. Additional experiments were done, including treatment with atropine sulfate (10 mg/kg s.c.) 30 min before pylorus-ligation and acidification of the duodenum with 2 ml 0.1 N HCl. The animals were killed (3-7 hr after experiments) and gastric contents collected and centrifuged. Determinations were made for pH, total acid output, and pepsin activity; the intestinal contents were examined quantitatively for volume and pH. The simultaneous ligation of individual points of the proximal small intestine, especially the end of the duodenum, in pylorus-ligated rats caused significant inhibition of gastric secretion (volume, acidity, and acid output). The participation of biliary secretion was negligible. The study suggests that several parts of the proximal small intestine appear to have pressure receptors which lead to the inhibition of gastric secretion and that the inhibition is independent of cholinergic nervous blocking and independent of hormonal influence (assumed to be produced by intestinal acidification); the need for further study is stressed.

2538 INVESTIGATION OF THE VASODILATOR AND ANTISECRETORY ROLE OF PROSTAGLANDINS IN THE RAT GASTRIC MUCOSA BY USE OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS. *(E.)* Main, I. H. M.; Whittle, B. J. R. (Sch. Pharm., Univ. London, England). *Br. J. Pharmacol.* 53(2):217-224, 1975.

The effects of non-steroidal anti-inflammatory drugs on gastric acid secretion and mucosal blood flow were studied in the rat to test the hypothesis that prostaglandins have a physiological role as negative feed-back inhibitors of acid secretion and as vasodilators in the gastric mucosa. The relation between inhibition of prostaglandin synthesis and the formation of mucosal erosions was also investigated. Acid output into the perfused gastric lumen was measured and mucosal blood flow determined simultaneously in Wistar rats. Following drug treatment, the rats were killed at various time intervals and the stomachs removed. Erosions, which formed only in the glandular mucosa, were counted and rated for severity. During resting conditions, indomethacin (30 mg/kg i.v.) had no significant effect on acid output, but reduced mucosal blood flow. When given in ulcerogenic doses (20 and 40 mg/kg), it caused a dose-dependent rise in pentagastrin-stimulated acid secretion, but decreased mucosal blood flow/U acid secretion. Pretreatment with indomethacin, phenylbutazone, or meclofenamate potentiated the secretory response to dibutyryl cyclic adenosine 3',5'-monophosphate. Indomethacin significantly reduced the mucosal prostaglandin-like activity at a time when mucosal erosion formation had reached steady levels. These results provide evidence that prostaglandins have a local role in the regulation of blood flow and acid secretion in the rat gastric mucosa, and suggest that non-steroidal anti-inflammatory drugs cause mucosal erosions by disrupting these processes.

2539 THE EFFECTS OF BURIMAMIDE AND METIAMIDE ON BASAL GASTRIC FUNCTION IN THE CAT. *(E.)* Harris, D. W.; Smy, J. R.; Reed, J. D.; Venables, C. W. (Dep. Pharm., Sunderland Polytech., England). *Br. J. Pharmacol.* 53(2):293-297, 1975.

The effects of burimamide and metiamide on basal gastric acid secretion and blood flow in the anesthetized cat and on acid secretion in the conscious cat were investigated. Burimamide or metiamide (2 mg/kg) was administered as a single i.v. injection, and gastric acid output was determined at 15 min intervals. In eight anesthetized cats, burimamide caused a 5-fold increase of acid secretion (30.9-150.9 μEq H^+/15 min) and increased mucosal blood flow 46% (18.7-27.4 ml/15 min). In nine conscious cats, the same dose of burimamide also increased acid secretion (24.1-174.1 μEq H^+/15 min). Metiamide, in six anesthetized cats, decreased acid secretion (51-0.8 μEq H^+/15 min) and mucosal blood flow (22.9-13.3 ml/15 min). When metiamide was given in a dose which inhibits pentagastrin-stimulated acid secretion (4 mg/kg i.m.) to six conscious cats, no significant changes were observed. Metiamide did not influence the amount of acid which diffused out of the stomach when instilled at pH 1.5-6.0. It is suggested that in increasing basal gastric secretion, burimamide stimulates acid secretion in the previously unstimulated stomach through release of some intermediary substance.

2540 SODIUM LOCALIZATION IN NORMAL, PENTAGASTRIN-STIMULATED AND SECRETIN-INHIBITED RAT GASTRIC MUCOSA. *(E.)* Kalahanis, N. G.; Das Gupta, T. K.; Nyhus, L. M. (Univ. Illinois Coll. Med., Chicago). *Fed. Proc.* 34(3):453, 1975.

Pancreas

2558 THE EFFECT OF CHRONIC HYPERGASTRINEMIA ON THE PANCREAS OF THE RAT. *(Fr.)* Chariot, J.; Lehy, T.; Nasca, S.; Dubrasquet, M. (Bichat Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 7:221-236, 1974.

The weight of the pancreas, its total DNA content, pancreatic enzyme activities and total protein, and pancreatic enzyme secretion were measured on fasting male Wistar CF rats with chronic hypergastrinemia induced by antrocolonic transposition. Controls consisted of intact rats, rats with gastric fistulas, and antrectomized rats. Studies were performed 14, 30, and 45 days and 6 months after antrocolonic transposition. Chronic hypergastrinemia had no effect on the weight of the pancreas. In comparison to the controls, total pancreatic DNA was significantly increased in rats with chronic hypergastrinemia 30 and 45 days and 6 months after surgery, while enzyme activities in pancreatic homogenates were decreased in some cases. At 14 days after surgery, pancreatic secretion of amylase, lipase, trypsin, and chymotrypsin did not differ significantly in rats with hypergastrinemia and those with gastric fistula and antrectomies. Areas of pancreatitis, which increased in frequency and severity with the time after surgery, were observed in rats with hypergastrinemia. A slight weight gain 6 months after antrocolonic transposition suggests that nutritional disorders accompany antrocolonic transposition and make long-term results more difficult to interpret. These results differ from those obtained previously by long-term treatment with pentagastrin. These discrepancies might be due to differences in the nature of the gastrin stimulants, gastrin doses, and ages of the rats. It is concluded that pancreatic secretion in the rat is not significantly affected by gastrin stimulation.

2559 THE ELECTROGENIC SODIUM PUMP IN THE HYPERPOLARIZING AND SECRETORY EFFECTS OF PANCREOZYMIN IN THE PANCREATIC ACINAR CELL. *(E.)* Kanno, T. (Fac. Vet. Med., Hokkaido Univ., Sapporo, Japan). *J. Physiol. (Lond.)* 245(3):599-616, 1975.

The hyperpolarizing effect of pancreatic secretagogues on pancreatic acinar cells was studied, along with the mechanism involved in the effect of pancreozymin on the acinar membrane potential. The transmembrane potential, effective membrane resistance, and amylase release were recorded simultaneously from the acinar cells of rat pancreas (taken from young male Wistar rats) perfused with Krebs-Henseleit solution. Continuous stimulation with 5 U pancreozymin/ml perfusing solution produced the highest and most prolonged amylase output, confirming the hyperpolarizing effect of the secretagogue. The hyperpolarizing effect disappeared under conditions of low ambient temperature, the absence of K$^+$, low Na concentrations, and in the presence of ouabain (10^{-5} M). In these environments, particularly with high concentrations of pancreozymin (200 U/ml), transient depolarization was frequently observed immediately after stimulation. All of these conditions which inhibited the secretory effect of pancreozymin are known to suppress the electrogenic Na pump. When a Krebs-Henseleit solution containing pancreomyzin was used to bathe the sectioned pancreas for 1 hr and then used to perfuse an isolated, non-sectioned pancreas, the bathing solution depolarized the acinar cells and decreased the effective membrane resistance. An increase in amylase release was observed at the initial perfusion with the bathing medium, but was not seen at the second perfusion. It is suggested that pancreozymin acts on the basal side of the membrane of the pancreatic acinar cell to produce dual effects. An increase in Na$^+$ and Ca^{2+} permeabilities leads to a rise in $[Ca^{2+}]_i$ which initiates the release of enzyme, and enhancement of the electrogenic Na pump maintains the Ca-influx and the consequent enzyme release.

2560 ATROPINE AND EXOCRINE PANCREATIC SECRETION IN ALCOHOL-FED DOGS. *(E.)* Tiscornia, O. M.; Palasciano, G.; Sarles, H. (Res. Unit Dig. Pathol., INSERM, Marseille, France). *Am. J. Gastroenterol.* 63(1):33-36, 1975.

The mechanism by which the stimulation of pancreatic secretion is triggered by acute i.v. ethanol in alcohol-fed dogs was studied. Five dogs were provided with chronic pancreatic and gastric fistulas (Thomas cannula). Ethanol (2 gm/kg diluted to 50% in isotonic saline) was administered daily through the gastric cannula, and the effects of acute i.v. ethanol injection (1.3 gm/kg) on the exocrine pancreatic secretion was tested before and 1.5, 3, 9, 12, and 17 months after the start of chronic alcohol intoxication. In all dogs, including one which had been subjected to truncal vagotomy, acute ethanol treatment elicited a rise in all cholecystokinin- and secretin-stimulated pancreatic secretion plateau values, particularly protein output. Cholinergic blockade by a continuous i.v. infusion of atropine inhibited primarily the protein component in the cholecystokinin- and secretin-stimulated juice. Atropine (1 mg/hr) superimposed on continuous secretin (1 CU/kg/hr) and CCK (3 u/kg/hr) injection prevented the excitatory effects of acute ethanol infusion on pancreatic secretion. Similar results had previously been found with the ganglionic blocking agent pentolinium. The data indicate that when given to alcohol-treated dogs, acute i.v. ethanol exerts its stimulatory effect on 'pancreon' *via* a cholinergic mechanism. This would be triggerd by stimulation of the parasympathetic hypothalamic centers and/or the autonomic intrapancreatic ganglia.

2561 EXOCRINE PANCREATIC FUNCTION IN URAEMIC RATS. *(E.)* Fleischer, K.; Kasper, H. (Med. Clin., Univ. Wurzburg, Germany). *Acta Hepatogastroenterol. (Stuttg.)* 21(6):398-403, 1974.

The exocrine pancreatic function in uremic rats was studied *in vivo* at 35 and at 100 days after 80-85%

nephrectomy. Exocrine pancreatic secretion was stimulated by continuous infusion of 25 U/kg/hr of secretin and 25 U/kg/hr of pancreozymin; pancreatic juice was collected at hourly intervals after cannulation of the pancreatic duct. The volume secreted in the uremic animals at 35 days increased by 83% during the first hr and 109% the second hr; the protein concentration and enzyme activities decreased, 39% for protein and 33% for lipase activity during the second hr. In animals which had been uremic for 100 days, pancreatic secretion was unchanged compared with controls. The hypersecretion of the exocrine pancreas in the initial phase of uremia appears to reflect the initial lesions of the exocrine pancreas.

2562 SECRETION OF CALCIUM IN PANCREATIC JUICE. *(E.)* Ceccarelli, B.; Clemente, F.; Meldolesi, J. (Dep. Pharmacol., Univ. Milan, Italy). *J. Physiol. (Lond.)* 245(3):617-638, 1975.

The origin of the calcium secreted by the pancreas was studied *in vivo* by analyzing the pancreatic juice secreted by the guinea pig in response to stimulation with secretin or cerulein, and by analyzing on a subcellular level the relation of the pancreatic tissue to its calcium secretory activity. Juice was collected from the cannulated pancreatic ducts of pentobarbitone-anesthetized male albino guinea pigs, into which tracers and secretagogue drugs were injected i.v. In agreement with previous findings, the concentration of calcium was low in the secretin-stimulated and high in the cerulein-stimulated juice. In the latter, calcium was proportional to protein. Following ^{45}Ca injection, the radioactivity in the blood plasma decreased rapidly and quasi-exponentially. The concentration of tracer in the secretin-stimulated juice remained relatively stable, at a level 1/3-1/4 of that in the plasma, whereas the concentration was 4- to 8-fold higher in the cerulein-stimulated juice. Switching from one type of secretion stimulation to the other resulted in a rapid shift in the level of radioactivity in the juice. In the secretin-stimulated juice, the time course of the juice:plasma radioactivity ratios observed after injection of [^{3}H]D-sorbital and ^{45}Ca were almost parallel. In the cerulein-stimulated juice, the ^{45}Ca ratios were at first lower than the corresponding [^{3}H]D-sorbital ratios. After 30 min they rose to very high values, the increase being followed by the appearance of newly synthesized [^{3}H]L-leucine-labeled proteins. The pancreatic tissue was rich in calcium, which was localized primarily in the zymogen granules and mitochondria; the soluble cytoplasm was low in calcium. The injected ^{45}Ca accumulated in the zymogen granules faster than the [^{3}H]L-leucine-labeled proteins. The ^{45}Ca:protein ratio of these organelles was considerably lower than that of the cerulein-stimulated juice. It is concluded that: 1) calcium is secreted into the pancreatic juice in two fractions, one associated with the electrolyte component, and the other with the juice protein; 2) zymogen granules are the major source of the latter fraction; and 3) the zymogen granule-associated calcium joins the exportable proteins some time after their synthesis.

2563 CALCIUM AND PANCREATIC SECRETION. I. SUBCELLULAR DISTRIBUTION OF CALCIUM AND MAGNESIUM IN THE EXOCRINE PANCREAS OF THE GUINEA PIG. *(E.)* Clemente, F.; Meldolesi, J. (Cent. Cytopharmacol., Natl. Res. Counc., Milan, Italy). *J. Cell. Biol.* 65(1):88-102, 1975.

Combined cytochemical and cell fractionation techniques were used to study the intracellular distribution of calcium in the guinea pig pancreas. Pancreatic homogenates and cell fractions from fasted male albino guinea pigs were assayed for calcium, magnesium, protein, cytochrome c oxidase, trypsin, and chymotrypsin. Most of the magnesium was associated with the rough microsomes (probably bound to the ribosomes) and the postmicrosomal supernatant of the acinar cells. Calcium was distributed among all particulate fractions, primarily the mitochondria, microsomes (especially smooth surfaced), zymogen granules, and the plasmalemma; it was found in low concentrations in the postmicrosomal supernatant. Most of the calcium recovered from the particulate reactions was membrane bound, the highest concentrations found in the membranes of the zymogen granules and in the plasmalemma. In control experiments, ^{45}Ca was added to the homogenization fluid during cell fractionation to determine the total amount of calcium artifactually adsorbed by each fraction. The results indicated that a considerable redistribution of calcium occurs during homogenization and cell fractionation. At least some of the resulting artefacts were estimated quantitatively and corrected calcium concentration data were obtained by subtracting the adsorbed calcium from the total calcium of the various fractions. The biochemical results were confirmed using the cytochemical antimonate technique carried out on the tissue and on isolated fractions. The results indicate that at least some of the calcium bound to the zymogen granule membrane might have a role in anchoring the membrane to the granule content, in preventing the activation of proteolytic zymogens within the granules, and in switching the conditions for the activation of the proteolytic zymogens from unfavorable, as in the zymogen granules, to favorable, as in the intestinal lumen.

2564 EXOCRINE PANCREATIC FUNCTION IN PROTEIN-DEFICIENT PATAS MONKEYS STUDIED BY MEANS OF A TEST MEAL AND AN INDIRECT PANCREATIC FUNCTION TEST. *(E.)* Gyr, K.; Wolf, R. H.; Imondi, A. R.; Felsenfeld, O. (Tulane Univ. Delta Primate Res. Cent., Covington, La.). *Gastroenterology* 68(3):488-494, 1975.

The influence of moderate protein deficiency and depletion on the exocrine pancreas was investigated in patas monkeys. Base line pancreatic function tests were performed while male and female monkeys were maintained on an adequate diet. Subsequently, they were put on a protein-free diet, and pancreatic function was again measured when the serum albumin had dropped to 2.8 g/100 ml or less. Pancreatic function was estimated by measuring enzymatic activities in the duodenal contents after a test meal and by determination of the urinary excretion of *p*-aminobenzoid acid (pancreatic function test) after oral ingestion of the chymotrypsin-labile peptide *N*-benzoyl-L-tyrosyl-*p*-aminobenzoic acid. The plasma proteins decreased rapidly during the first 2 weeks on the protein-free diet, after which the globulin concentration leveled off at 2.9 g/100 ml. The albumin level continued to drop slowly, reaching 2.8 g/100 ml after 13.8 weeks. In five animals, protein deficiency caused no clinical symptoms except weight loss. In the other four monkeys, anorexia and hair loss were noted; two of these animals died and both showed atrophy of the pancreatic acinar cells. Significant decreases in the trypsin, lipase, amylase, and chymotrypsin activities of the duodenal samples were observed during protein deficiency. The urinary excretion of *p*-aminobenzoic acid was also significantly reduced. The two tests of pancreatic function correlated well. The data indicate that exocrine pancreatic secretion can be seriously impaired even at a moderate level of protein deficiency and that it may not always be reversible. Therefore, function tests must be evaluated with caution when hypoproteinemia is present.

2565 SECRETION OF IMMUNOREACTIVE GASTRIN FROM THE ISOLATED, PERFUSED CANINE PANCREAS.

(E.) Rehfield, J. F.; Iversen, J. (Bispebjerg Hosp., Copenhagen, Denmark). *Horm. Metab. Res.* 6(4):260-264, 1974.

The concentration of immunoreactive gastrin was measured radiochemically in the perfusate from 11 perfusions of the isolated canine pancreas using rabbit antibodies raised against synthetic human gastrin. In 9 of 11 perfusions the concentration of immunoreactive gastrin was measurable (basal level, 7 pM/liter). During 10 min perfusions with arginine hydrochloride (1 mM/liter) and acetylcholine (10 µM/liter), immunoreactive gastrin concentrations rose to 4.5 and 7 pM/liter above the basal level, resp. Infusion of atropine in a concentration of 25 µM/liter prior to and during 2 infusions with acetylcholine lowered immunoreactive gastrin concentration from 8.4 to 5.0 pM/liter. Atropine did not prevent the stimulation of immunoreactive gastrin release by acetylcholine (10 µM/liter for 10 min). Alteration of glucose concentrations in the perfusion medium from 1.4 to 8.3 and later to 16.7 mM/liter had no effect on immunoreactive gastrin concentrations. Epinephrine (10 nM/liter) did not stimulate immunoreactive gastrin secretion. It was concluded that immunoreactive gastrin is present and may be released from the canine pancreas in response to cholinergic and aminogenic stimuli.

2566 CHRONIC ALCOHOLISM AND THE GASTRIN PHASE OF PANCREATIC SECRETION. *(Fr.)*

Palasciano, G.; Tiscornia, O. M.; Dzieniszewski, J.; Teixeira, A. S.; Cavarzan, A.; Sarles, H. (Res. Unit Gastrointest. Dis., INSERM, Marseille, France). *Biol. Gastroenterol. (Paris)* 7:209-213, 1974.

The effect of 15% ethanol (1.3 g/kg p.o. through a stomach tube) on pancreatic secretion was studied in 3 dogs which had been given alcohol (2 g/kg/day p.o. through a stomach tube) for 2 yr and in 5 controls. All the dogs had gastric and duodenal fistulas. The gastric fistula was left open during the experiments to prevent the gastric contents from entering the duodenum. When pancreatic secretion was stimulated with secretin (1.0 U/kg/hr) and cholecystokinin-pancreozymin (3.0 U/kg/hr), infused simultaneously i.v., acute administration of ethanol significantly increased the pancreatic protein output in both groups of dogs. The protein output increased 70.9% in alcohol-fed dogs and 46.0% in controls. Increases also occurred in the volume of secretion, bicarbonate output, and protein concentration. Increases in the volume of secretion and the protein concentration were only significant for alcohol-fed dogs, while the increase in bicarbonate output was not significant in either group. The findings in this and previous studies suggest that increased secretion of pancreatic proteins, which is characteristic of the alcoholic pancreas, is due more to increased release of cholecystokinin-pancreozymin than to release of gastrin.

2567 EFFECTS OF CHRONIC ALCOHOLISM ON THE SYNTHESIS OF PANCREATIC ENZYMES IN THE RAT BEFORE AND AFTER ENDOGENOUS STIMULATION OF SECRETION.

(Fr.) Dagorn, J. C.; Figarella, C.; Michel, R.; Sarles, H. (Res. Unit Gastrointest. Dis., INSERM, Marseille, France). *Biol. Gastroenterol. (Paris)* 7:201-208, 1974.

The rate of pancreatic enzyme synthesis and pancreatic enzyme activities were measured in water- and alcohol-fed fasting male Wistar CF rats given balanced and high-fat diets after pancreozymin-like stimulation by p.o. instillation of 2 ml oleic acid. Amylase, lipase, and potential chymotrypsin activities were measured on supernatant from pancreatic homogenates, and the rate at which ^{14}C-valine was incorporated into total pancreatic protein was measured on the homogenates themselves. Alcoholic rats received 20% alcohol *ad libitum* in place of drinking water for 2 or 8 months and either a high-fat or balanced diet. Before oleic acid stimulation the rate at which pancreatic proteins were synthesized was essentially the same in alcoholic and water-fed rats given balanced or high-fat diets, but the activities of all 3 pancreatic enzymes were increased in alcoholic rats. The rate of protein synthesis decreased significantly in alcoholic rats fed a high-fat diet 60 min after administration of oleic acid. This decrease was observed after 2 months of a high-fat diet but was more pronounced after 8 months. No significant change in the rate of protein synthesis occurred in the remaining 3 groups of rats (high-fat diet and water, balanced diet and water, and balanced diet and alcohol) after oleic acid stimulation. The decrease which occurred in pancreatic enzyme activity after oleic acid stimulation was less pronounced in alcoholic rats than in those given water, but this difference was not significant. Changes in the rate of pancreatic protein synthesis appear to be preceded by changes in the response of the pancreas of alcoholic rats to stimulation, confirming results obtained previously on dogs.

2568 PANCREATIC ACINAR CELLS: IONIC DEPENDENCE OF ACETYLCHOLINE-INDUCED MEMBRANE POTENTIAL AND RESISTANCE CHANGE.

(E.) Nishiyama, A.; Peterson, O. H. (Inst. Med. Physiol. C, Univ. Copenhagen, Denmark). *J. Physiol. (Lond.)* 244(2): 431-465, 1975.

Current-voltage relations and the effect of ion replacements on the potential and resistance changes evoked by adding acetylcholine to the bathing fluid of isolated segments of mouse pancreas were investigated by injecting rectangular de- or hyperpolarizing current pulses through the recording microelectrode. Within a relatively wide range (-20 to -70 mV) there was a linear relation between injected current and change in membrane potential. The slope of such linear curves corresponded to an input resistance of about 3-8 MΩ. The membrane time constant was about 5-10 msec. Acetylcholine depolarized the cell membrane and caused a marked reduction of input resistance and time constant. The minimum latency of the acetylcholine-induced depolarization (applied locally to pancreatic acini by micro-iontophoresis) was 100-300 msec. Maximal depolarization was about 20 mV. The effect of this local acetylcholine application was abolished by atropine (1.4 x 10^{-6} M). The blocking effect of atropine was fully reversible. Replacing the superfusion fluid Cl by sulfate or methylsulfate caused an initial short-lasting depolarization. The amplitude of the acetylcholine-induced depolarization was enhanced in this state. Replacing extracellular Na by Tris caused an initial short-lasting hyperpolarization. In the steady state the resting potential was slightly lower than normal. The depolarizing effect of acetylcholine was immediately reduced as was the acetylcholine-induced change in resistance. Adding ethylene glycol-bis-(β-amino ethyl ester)N,N'-tetro acetic acid to a normal Na-containing Ca-free solution depolarized the cell membrane by about 5-10 mV and reduced the input resistance. Acetylcholine still evoked marked depolarization and reduction of input resistance. Omitting K from the superfusion fluid caused a slight cell membrane hyperpolarization. Acetylcholine caused a marked depolarization and resistance reduction. Readmitting K to a K-free solution after several hr of K deprivation caused a very marked hyperpolarization (20-30 mV) not accompanied by any change in input resistance or time constant. It is concluded that acetylcholine acts on the acinar cells by increasing the conductance of the plasma membrane to Na and K and possibly also to other ions. There is, however, no evidence for an acetylcholine-induced change in membrane Ca conductance. The importance of extracellular Ca may be the control of the $P_{Na}:P_K$ ratio.

2569 EFFECT OF AGE AND LONG-TERM DIET ON EXOCRINE PANCREAS OF THE RAT.

(E.) Snook, J. T. (Dep. Hum. Nutr. Food, Cornell Univ., Ithaca, N.Y.). *Am. J. Physiol.* 228(1):262-268, 1975.

The effects of age and diet on rat pancreas enzyme and nucleic acid levels were analyzed in experiments designed to investigate pancreas composition and function between weaning and senescence, and possible factors responsible. Male Charles River rats were maintained on commercial cereal chow, were fed a stimulatory test diet of 15% whole egg protein for 1 week prior to killing by chloroform, and the pancreas was extracted. Pancreas weight, nucleic acid levels and pancreatic enzyme levels were measured. Pancreas weight declined from 0.78% at 4 weeks to 0.35% at 1 yr as a proportion of body weight. At 28 months, average body weight was 200 g less than that of 19-month-old rats while pancreas weight and total DNA were significantly greater compared to 12-month-old rats. Pancreatic lipase, chymotrypsinogen and trypsinogen were reduced more than 65% in 28- as compared to 12-month-old rats; amylase had disappeared. The decline in enzymes occurred sometime after 19 months. In the second experiment semipurified diets high in sucrose, starch or butterfat were fed to rats from 9-24 months of age. The physiological condition of rats in the fat and sucrose group appeared poorer than 28-month-old rats in the first experiment. The high fat diet rats had significantly less chymotrypsinogen and trypsinogen than 9-month-old control groups, while the sucrose, starch and 9-month-old control groups did not differ significantly in total enzyme content. Enzyme concentrations were generally lower in aged rats; this was compensated for by increase in pancreas size. Digestion of whole egg protein (3 g/day) was not impaired even in rats with a 50-70% reduction in total pancreatic protease, in agreement with previous findings that a decrease in the functional reserve capacity of the pancreas may not be of metabolic significance.

2570 EFFECTS OF CHRONIC ETHANOL ADMINISTRATION ON CANINE EXOCRINE PANCREATIC SECRETION. FURTHER STUDIES.

(E.) Tiscornia, O.; Palasciano, G.; Sarles, H. (Res. Unit Dig. Pathol., INSERM, Marseille, France). *Digestion* 11(3/4):172-182, 1974.

Ethanol-induced modifications of pancreatic secretion in the dog were studied up to one year's exposure. Five dogs were given chronic pancreatic fistulae, the accessory duct ligated in each case, and Thomas cannulas were inserted into the stomach. After an 18 hr fast the major pancreatic duct was cannulated and the secretion collected at 20 min intervals. Ethanol and secretin (1.0 CU/kg/hr) alone or combined with cholecystokinin (3.0 U/kg/hr) were infused into the saphenous veins. After standardization, 2.0 g/kg 50% ethanol in isotonic saline was administered by the gastric cannula at the same hr daily. Pancreatic secretory response to acute i.v. ethanol infusion was determined by two methods. In one, under continuous perfusion of secretin, a 1.3 g/kg infusion of ethanol was followed by daily intragastric administration of 2.0 g/kg of ethanol. Pancreatic response to the same conditions was retested at 3 and 6 months. In the other method, under continuous perfusion of secretin and cholecystokinin a 1.3 g/kg ethanol infusion was given. Changes induced by chronic alcohol feeding on the plateau pancreatic secretory values were evaluated, with secretin alone or with secretin and cholecystokinin, at 6 weeks, and 3, 9, and 12 months. Pancreatic juice determinations included flow rate, and the outputs and concentrations of bicarbonate, pretein, and lipase. Acute i.v. ethanol inhibited all constituents of exocrine pancreatic juice during the non-alcoholic stage in both experiments, but more markedly with secretin alone than when it was combined with cholecystokinin. The effects were greater on protein and lipase than the alkaline components; secretin alone resulting in a fall of bicarbonate output of 42.2% 40 min after ethanol injection while protein and lipase fell 73.5% and 61.2%, resp. Secretin and cholecystokinin resulted in a fall of bicarbonate output to 21.6% after 60 min, while protein and lipase 27.0% and 33.0%, resp. After 3 months ethanol injection no longer caused any significant inhibition. After 12 months, the effects were reversed, and almost all parameters showed significant increases. Chronic alcohol feeding with secretin alone caused an increase in bicarbonate concentration after 3 months. By 12 months, concentration and output of protein and lipase were significantly depressed. With secretin and cholecystokinin, at 6 weeks, 3, 9, and 12 months, volume and bicarbonate output were higher than during the non-alcoholic period. Protein values rose and after 12 months dropped to pre-treatment values. Lipase values also diminished after 12 months. It is concluded that chronic alcohol feeding as opposed to acute causes an inversion of exocrine pancreatic response and modifies plateau levels of secretion in response to secretin to cholecystokinin.

2571 SUBCUTANEOUS SECRETIN IN DOGS: INFLUENCE OF SOLVENT AND VOLUME OF SOLVENT. *(E.)*

Verine, H. J.; Grossman, M. I. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Acta Hepatogastroenterol.* (Stuttg.) 22(1):35-40, 1974.

The effects of the solvents carboxymethylcellulose and gelatin on the magnitude and duration of action of s.c. secretin were tested. Three dogs were given a Thomas cannula and a pancreatic fistula at least a month before the experiment. The dogs were fasted for 18 hr, and 5.6 or 2.8 U/kg secretin were injected s.c. under the loose skin of the neck at one of three sites (2 ml/site). The secretin was dissolved in either 0.001 M HCl-saline, 16% gelatin, or 10% carboxymethylcellulose. Each of the 12 combinations of doses, solvents, and volumes of solvent were tested on separate days, one time in each of the three dogs. During each test the dogs received a continuous i.v. saline infusion (24 ml/hr). The volume of pancreatic juice was recorded every 10 min, and bicarbonate concentration was determined by titration. Peak output was not significantly related to the dose, solvent or solvent volume, but the time at which peak output occurred was related to dose and solvent. The peak occurred at 56 min with the 75 U dose, and at 74 min with the 150 U dose; and occurred at the earliest with saline and at the latest with gelatin. Duration of secretion at over 75% of peak was for 20-30 min with saline, but lasted for 90 min with gelatin or carbomethylcellulose. This was dependent on dose (49% greater with 150 U than with 75) and on solvent (84% greater with gelatin and 29% greater with carboxymethylcellulose than with saline). Duration of total response was 25% longer with the higher dose; 84% longer with gelatin and 36% longer with carboxymethylcellulose than with saline; and 27% longer with 6 ml than with 2 ml. Total bicarbonate output was 38% greater with the higher dose, 38% greater with gelatin and 10% greater with carboxymethylcellulose than saline, and 17% greater with the larger volume. It is concluded that carboxymethylcellulose, and to a greater extent gelatin, greatly enhance the magnitude and length of response to s.c. secretin.

2572 ELECTROPHORETIC CHARACTERIZATION OF PORCINE PANCREATIC (PRO)ELASTASES A AND B. *(E.)*

Ledoux, M.; Lamy, F. (Fac. Med., Univ. Sherbrooke, Canada). *Can. J. Biochem.* 53(4):421-432, 1975.

Two porcine pancreatic zymogens (proelastases A and B) and the products of their activation by trypsin were characterized by polyacrylamide-gel electrophoresis, and the effect of these proelastases and trypsin on elastin was studied. The proelastases were purified and separated by free electrophoresis on a sucrose gradient. After activation by trypsin, both enzymes were able to completely hydrolyze elastin. Proelastase B, but not A, also had an esterolytic activity towards *N*-acetyl-L-tyrosine ethyl ester. To further identify the products of activation of proelastases A and B, the products were tagged with radioactive diisopropylfluorophosphonate and separated by polyacrylamide-gel electrophoresis. Proelastase A gave only one active species, pancreatopeptidase E, but three distinct proteins were obtained from proelastase B; one of the products of activation of B had the same mobility as its precursor. Elastases A and B exhibited a synergism when acting together on an elastin preparation from which the microfibrils were removed; a smaller degree of synergism was noted when an alkaline-treated elastin was used as substrate, and there was only a slight synergism when a commercial elastin preparation was used. There was little additional synergism when trypsin was added to mixtures of A and B, and there was no synergism noted when chymotrypsin was added to mixtures of A and B. The results indicate that although elastase B resembles α-chymotrypsin, it is a different enzyme; similarly, it is unlikely that proelastase B is the same as chymotrypsinogen B or C.

2573 PANCREATIC DUCT ABRASION AND SELECTIVE ASPIRATION OF SECRETION — EXPERIMENTS IN DOGS. *(E.)*

Weidenhiller, S.; Stolte, M.; Koch, H.; Schwamberger, K.; Flugel, H. (Dep. Med., Univ. Erlangen-Nuremberg, Erlangen, Germany). *Endoscopy* 7 (1):10-17, 1975.

A method of abrading the pancreatic duct to obtain fresh cellular material for diagnosis is presented. Nine dogs were laparotomized and the duodenum opened. A size three Fogarty catheter was inserted into the main pancreatic duct as far as possible. After injection of 2 IU/kg secretin, and pancreatic secretion through the papilla, the balloon of the catheter was partially expanded and drawn through a short section of duct several times. In three dogs the stimulated secretion was aspirated with the abraded material by means of a 20 ml syringe through a Teflon tube covering the catheter, and was centrifuged and stained. In all dogs, the balloon was inflated and drawn through the entire length of the duct several times. The air pressure was adjusted in different cases to vary the strength of abrasiveness from gentle to aggressive. The balloon was deflated, withdrawn, and rolled on glass slides which were subsequently treated with Pappenheim's stain. Four dogs were sacrificed immediately, one at four days, one at seven days, and three dogs at three weeks, and the pancreatic duct fixed, stained and examined by light microscopy. Intubation of the duct and aspiration of secretion was successful in all cases. In both aspirate and smear preparations, large numbers of connected duct epithelial cells as well as individual cells were obtained. Macroscopically, none of the ducts showed any pathological changes. Microscopically, the ducts of the dogs sacrificed immediately showed the layer of columnar epithelium had been almost completely abraded, but the continuity of the basement membrane was intact. Four days after the abrasion, the duct was lined completely with narrow cylindrical cells, easy to differentiate, and with occasional fine gaps between them. After seven days the cells were further matured and more compactly united. Of two dogs given gentle abrasion, one after three weeks showed incomplete layering of the regenerated epithelium, fine gaps, and multiple broad defects between cells, but in the other the duct epithelium was completely regenerated and intact. Another dog, three weeks after aggressive abrasion, showed epithelium almost indistinguishable from normal. It is concluded that good cytological material for diagnosis can be obtained successfully by this method of duct abrasion, and that the epithelium will be regenerated within three weeks.

2574 EXPERIMENTAL CONTRIBUTION TO THE STUDY OF PANCREATIC POLYSERITIS. TRANSDIAPHRAGMATIC AND LYMPHATIC DIFFUSION OF TRYPSIN.

(Fr.) Warter, J.; Storck, D.; Warter, A. (Univ. Hosp. Cent., Strasbourg, France). *C. R. Soc. Biol. (Strasburg)* 108(6/7):860-865, 1974.

Intra- and retroperitoneal injections of trypsin alone, trypsin and Chinese ink, and Chinese ink in physiological solution were administered to rats (type unspecified) in order to determine the zones of passage of trypsin from the peritoneum into the pleural cavities. Both intra- and retroperitoneal injection of trypsin alone produced hemorrhagic overflow in the peritoneum and the pleura, with radial hemorrhage striation on both sides of the diaphragm but more intensely on the peritoneal side. There was intense vascular congestion in the subperitoneal space and on the intestinal chorion, cell lysis at the apex of the villi, edema, and subserosal hemorrhage. Such lesions are evidence of the direct transdiaphragmatic passage of trypsin injected into the peritoneum. Injection of trypsin with Chinese ink into the peritoneal cavity produced dyeing of the areas seen to be affected by injection of trysin alone. Also dyed were were the ganglia of the superior mediastinum; the fringes of the omentum; the Kupffer cells; the mesothelial cells of the peritoneum; the diaphragmatic, parietal, and visceral pleura; and the alveolar sacs in the lungs. This provides evidence of lymphatic and pleuro-pulmonary paths for resorption. Injection of trypsin and Chinese ink into the pleural cavity confirmed that trypsin does not pass from the pleura into the abdomen, although it is resorbed by a pleuropulmonary path. Injection of Chinese ink in physiological solution provides confirmation of the lymphatic resorption of trypsin and Chinese ink from both the peritoneal and pleural cavities.

2575 EFFECT OF A SOYBEAN DIET ON ENZYME CONTENT AND ULTRASTRUCTURE OF THE RAT EXOCRINE PANCREAS.

(E.) Folsch, U. R.; Winckler, K.; Wormsley, K. G. (Dep. Med., Univ. Gottingen, Germany). *Digestion* 11(3/4):161-171, 1974.

The enzyme content and ultrastructure of exocrine pancreas was studied in rats fed raw soybean flour with active trypsin inhibitor, or heat-inactivated soybean flour. Two groups of five Wistar rats each were fed a diet containing either raw or heat-inactivated soybean flour for 20 days, while controls were fed a standard diet containing 42% carbohydrates, 19% protein, and 4% fat. After 20 days, all rats were killed following a 24 hr fast. Electron microscopic studies were done on pancreatic tissues from eight additional rats, given the same diets as above, but given in addition a 7.5 or 60 IU/kg/hr dose of cholecystokinin with a 0.5 CU/kg/hr dose of secretin for 4 hr before histological examination. The tissues were fixed in Karnowsky's solution, postfixed in 1% osmium tetroxide, and stained with toluidine blue for light microscopy, or uranyl acetate and lead citrate for electron microscopy. The pancreas was removed, weighed, homogenized, and analyzed for trypsin, amylase, lipase, and protein. The net weight of the pancreas/100 g body weight in the rats fed raw soybean flour was double that in those fed either heat-inactivated flour or standard diet. The latter two did not differ significantly. The raw flour-fed rats showed a significantly higher protein content (404 mg/pancreas), than standard diet-fed (161 mg) or heat-inactivated-fed rats. Amylase activity (4707 U/total pancreas) was significantly less in rats given the inactivated flour, than those given the standard diet (13,190 U) or given raw flour (11, 773). Activity of trypsin and lipase was significantly greater in inactivated flour-fed rats (19,403 and 5806, resp.) than standard diet-fed rats (9331 and 1642, resp.). Total pancreatic content of amylase and trypsin was greater in raw flour fed rats than inactivated flour-fed rats, but total lipase content did not vary significantly. Electron microscopy of tissues from rats not given exogenous hormones showed greatly increased numbers of zymogen granules in the acinar cells of the rats fed raw flour.

These were found in the basal as well as the apical parts of the cells. The rats on the other two diets showed no morphological changes. The rats on standard or inactivated diets showed a marked diminution in acinar cell zymogen granule content. The acinar cells of the raw flour-fed rats showed as many granules as non-hormone stimulated standard and inactivated-fed rats. It is concluded that raw soybean flour increases the total protein content by increasing enzyme and non-enzyme proteins; but except for an increase in the number of zymogen granules, cellular structures are not altered.

SECRETION AND METABOLISM

Hepatobiliary Tract

2595 DRUG INDUCTION OF HEPATIC GLUTATHIONE S-TRANSFERASES IN MALE AND FEMALE RATS. *(E.)* Kaplowitz, N.; Kuhlenkamp, J.; Clifton, G. (Nav. Reg. Med. Cent., Oakland, Calif.). *Biochem. J.* 146(2): 351-356, 1975.

The induction of the glutathione S-transferases by phenobarbital and polycyclic aromatic hydrocarbons was studied in male and female rats in order to examine similarities between these enzymes and ligandin, and also to identify a potentially inducible cytosolic enzyme system of importance in drug metabolism. Sprague-Dawley rats were given phenobarbital (2-8 mg in 0.9% NaCl) and 3,4-benzopyrene or 3-methyl-cholanthrene (1 mg in corn oil i.p. twice a day). The animals were killed 24 hr after the last dose; liver homogenates were prepared and centrifuged, then the supernatant fractions (cytosol) were collected for study. Administration of phenobarbital resulted in 60-80% increase in S-aryl and S-aralkyl enzyme specific activities, whereas the S-epoxide and S-alkyl activities were increased by 30-40%. In following the sequence of induction, the former 2 activities reached peak activities before an increase in the latter 2 activities was observed. Both 3-methylcholanthrene and 3,4-benzopyrene induced these 4 enzymic activities, but to a lesser degree than did phenobarbital (with the exception of S-epoxide activity). Significantly lower enzyme specific activities were found for 3 of the activities studied in female rats but no difference observed in S-alkyltransferase activity; however, the proportional increase in the enzymic activities in response to phenobarbital was the same in males and females. The findings demonstrate the inducibility of 4 glutathione S-transferase activities by phenobarbital and the 2 polycyclic aromatic hydrocarbons, and they further support the possibility that ligandin is part of the group of glutathione transferases.

2596 PROTECTION OF RATS AGAINST THE HEPATOTOXIC EFFECT OF PARACETAMOL. *(E.)* Gazzard, B. G.; Hughes, R. D.; Portmann, B.; Dordoni, B.; Williams, R. (King's Coll. Hosp. Med. Sch., London, England). *Br. J. Exp. Pathol.* 55(6):601-605, 1974.

The effectiveness of a number of agents against the hepatic damage caused by paracetamol was studied in rats. With the exception of the control group, all the animals received phenobarbitone (1 g/liter) in their drinking water and paracetemol (2.5 g/kg) *via* an intragastric tube immediately following the administration of the protective agents under study: i.v. glutathione (40 mg/kg); propranolol (40 mg/kg); thioctic acid (5 mg/kg); p.o. cysteamine (300 mg/kg); i.p. cysteamine (300 mg/kg); i.p. α-tocopherol acetate (400 mg/kg). Livers were removed 48 hr after administration of agents for histological assessment and determination of cytochrome P-450. The paracetamol-induced liver damage with corresponding reduction in levels of cytochrome P-450 was completely prevented by the oral cysteamine. The levels of cytochrome P-450 were maintained following i.p. α-tocopherol, but it had less effect on the histological evidence of liver damage. Glutathione, propranolol, and thioctic acid did not prevent liver damage, although the number of areas of necrosis (believed to be the result of infarction) was reduced except with glutathione. It was concluded that the degree of protection against liver damage afforded by the agents under study cannot be explained until the mode of action of the reactive metabolite of paracetamol is further understood.

2597 EFFECTS OF HYPOPHYSECTOMY OF LIVER DONOR ON NET SYNTHESIS OF SPECIFIC PLASMA PROTEINS BY THE ISOLATED PERFUSED RAT LIVER. MODULA-

TION OF SYNTHESIS OF ALBUMIN, FIBRINOGEN, α_1-ACID GLYCOPROTEIN, α_2-(ACUTE PHASE)-GLOBULIN, AND HAPTOGLOBIN BY INSULIN, CORTISOL, TRIIODOTHYRONINE, AND GROWTH HORMONE.

(E.) Griffin, E. E.; Miller, L. L. (Univ. Rochester Sch. Med. Dent., N.Y.). *J. Biol. Chem.* 249(16):5062-5069, 1974.

The isolated adult male Sprague-Dawley rat liver perfused for 12 or 24 hr was used to study effects of total hypophysectomy of the liver donor, and of added cortisol, bovine growth hormone, insulin, and triiodothyronine on the net biosynthesis of 5 specific plasma proteins. Cortisol (5 mg) was added to the perfusion medium at the outset and by continuous infusion (a total of 10 mg) during the 24-hr period. Two of the other 3 hromones were added with the cortisol in the following quantities: insulin, 5 U initially and 13.6 U by infusion; growth hormone, 0.5 mg and 2 mg; and triiodothyronine, 2 μg and 4 μg. Plasma proteins released into the perfusion medium were measured by the single radial diffusion technique. With all 4 hormonal supplements, livers from fed hypophysectomized rats perfused at pH 7.10 synthesized about 50% less albumin than livers from normal donors while synthesis of fibrinogen, acid glycoprotein, and haptoglobin was close to that observed in normals. Fibrinogen synthesis in the absence of triiodothyronine was not different from that with the 4 hormones; however, deletion of either insulin or growth hormone resulted in a small but significant decrease in net synthesis below that seen with the 4 hormones. Deletion of either triiodothyronine, growth hormone, or insulin was associated with failure to increase synthesis of haptoglobin above that seen in the absence of all hormones at 12 hr, and at 24 hr was only 50% of that with all 4 hormones. In the absence of hormone supplements, synthesis of α_2-(acute phase)globulin by livers from hypophysectomized donors was undetectable. With all 4 hormones, synthesis of this protein was not significantly different from that by livers of normal donors. Omission of either triiodothyronine, insulin, or growth hormone diminished the net synthesis of the protein in a manner similar to that observed with haptoglobin. Omission of insulin or growth hormone caused a small but significant decrease in net uptake of free amino acid nitrogen. The absence of insulin was associated with increased urea production, negative nitrogen balance, and reduced incorporation of L-[1-^{14}C]leucine into hepatic protein. It is concluded that the regulation of the synthesis of several acute phase plasma proteins in livers from hypophysectomized rats is qualitatively and quantitatively as sensitive to the hormones tested as in livers from normal rats, the synthesis of α-acid glycoprotein being an exception because it is maximal in livers from hypophysectomized rats and is not further increased by hormones.

2598 COMPARATIVE STUDY OF THE ABSORPTION, ELIMINATION AND ACUTE HEPATOTOXIC ACTION OF ETHANOL IN GUINEA PIGS AND RATS.

(E.) Strubelt, O.; Siegers, C. P.; Breining, H. (Med. Univ., Lubeck, Germany). *Arch. Toxicol. (Berl.)* 32(2):83-95, 1974.

The hepatotoxic effects and kinetics of ethanol were studied in male guinea pigs and Wistar rats. In fed guinea pigs, an oral dose of 6.4 g/kg of ethanol given as a 40% solution (v/v) produced a maximal blood alcohol level of 6.8 mg/ml, whereas in fed rats, blood alcohol levels after the same dose did not exceed 2.1 mg/ml. Maximal blood alcohol levels in fasted animals occurred 1-4 hr after an oral load of 4.8 g/kg of ethanol and were 6.3 mg/ml in guinea pigs and 3.7 mg/ml for rats. However, i.v. injected ethanol (1 g/kg) was eliminated at the same rate in both species (275 mg/kg/hr), and alcohol dehydrogenase activity of the liver related to body weight was 20% greater in guinea pigs than in rats. Therefore, absorption of ethanol occurred at a much slower rate in rats than in guinea pigs. This is possibly due to the fact that high ethanol concentrations strongly delay emptying of the rat stomach. Lowering the ethanol concentration accelerated absorption rate in the rat. However, even after gavage of a 10% solution, peak levels of blood alcohol were still lower by 36% in rats than in guinea pigs. In guinea pigs, increased activities of SGOT, SGPT, and glutamate dehydrogenase occurred after an oral dose of 4.8 g/kg or 6.4 g/kg of ethanol, resp. SGOT increased after 1.6 g/kg of ethanol p.o. After 6.4 g/kg of ethanol given to rats serum transaminase levels increased only slightly, and glutamate dehydrogenase activity not at all. Vacuolar degeneration was the morphological substrate of ethanol-induced liver damage in guinea pigs and rats. In guinea-pigs, it occurred after 1.6 g/kg of ethanol, whereas in rats only after 6.4 g/kg. It is concluded that the guinea pig is more suitable than the rat as a model for alcohol toxicity.

2599 DETERMINATION OF BILE ACID POOL SIZE IN MAN: A SIMPLIFIED METHOD WITH ADVANTAGES OF INCREASED PRECISION, SHORTENED ANALYSIS TIME, AND DECREASED ISOTOPE EXPOSURE.

(E.) Duane, W. C.; Adler, R. D.; Bennion, L. J.; Ginsberg, R. L. (Phoenix Indian Med. Cent., Ariz.). *J. Lipid Res.* 16(2):155-158, 1975.

A simplified method is described for estimating the bile acid pool size in man. The procedure, studied in 26 healthy volunteers aged 19-34, involves either i.v. or intragastric infusion of 1-5 μCi ^{14}C- or 3-15 μCi ^{3}H-cholic acid 6 hr after a light supper. Contents from the descending duodenum are withdrawn by tube the next morning following stimulation of gallbladder contraction with protein hydrolysate. Total bile acid pool size (P_T) is calculated from total bile acid concentration (B_T), the radioactivity administered (dpm_A) and the concentration of radioactivity in the bile acids (dpm_T) according to the formula: $P_T = dpm_A\ (B_T/dpm_T)$. The precision of this method (±2.6%), which is not influenced by the route of administration of cholic acid nor by the type of radioactive label, compares favorably to that of the Lindstedt method (±7.9%). Other advantages over the Lindstedt method include the requirement for only one duodenal intubation and the necessity of using only 12.5-25% of the radionuclide dose. In 16 comparisons, pool size measured 13.7% higher by this method than by the Lindstedt procedure, a difference predicted by extrapolation of the cholic acid specific activity of the Lindstedt method to time zero.

2600 STUDIES ON UREA CYCLE ENZYMES IN RAT LIVER DURING ACUTE URAEMIA. *(E.)* Hoppe-Seyler, G.; Maier, K. P.; Schollmeyer, P.; Frohlich, J.; Talke, H.; Gerok, W. (Dep. Intern. Med., Univ. Freiburg, Germany). *Eur. J. Clin. Invest.* 5(1):15-20, 1975.

Urea cycle enzyme activities were measured in female albino Sprague-Dawley rats 12 and 48 hr after ligature of both renal pedicles. After 12 hr, ornithine carbamyl transferase specific activity of liver homogenates was elevated by 30% whereas, after 48 hr, specific activities of both this and argininosuccinic acid synthetase were increased by 55% and 33%, resp. Activities of argininosuccinic acid lyase, glutamic-aspartic-transaminase, glutamic-alanine-transaminase and ornithine-δ-amino-transferase were unaffected except for a 50% decrease after 48 hr in ornithine-δ-amino-transferase. Except for the decrease in ornithine-δ-amino-transferase, changes in activities of the other enzymes were not so marked as seen during prolonged starvation. Based on previous findings which failed to detect changes in liver ornithine concentration in the uremic state, it is concluded that the present results are not consistent with the concept that accelerated urea production in the liver of acutely uremic rats is due to increased liver ornithine concentration secondary to decreased ornithine-δ-amino-transferase activity.

2601 MULTIPLE HEPATIC EXCRETORY MECHANISMS FOR ORGANIC ANIONS. A STUDY WITH SUCCINYLSULFATHIAZOLE AND TAUROCHOLATE IN THE RAT. *(E.)* Bailey, D. G.; Johnson, G. E. (Dep. Pharmacol., Univ. Toronto, Canada). *Can. J. Physiol. Pharmacol.* 53(1): 97-103, 1975.

The interactions during biliary excretion of succinylsulfathiazole and taurocholate were studied in male Wistar rats. Following infusion of ^{14}C-succinylsulfathiazole (100 mg/kg) or ^{3}H-taurocholate (56 mg/kg) separately over a 3-5 min period, all of the taurocholate but only about 10% of the succinylsulfathiazole was excreted in the bile over 40 min. Concomitant administration of the 2 substances reduced the amounts of taurocholate and succinylsulfathiazole excreted into the bile to 81% and 8%, resp., after 40 min. Bile flow rate was increased about 1.5-fold following administration of either substance alone and about 3-fold when both were given together. Bile concentration of ^{3}H-taurocholate was significantly less (18.9 mg/g wet weight) in animals receiving both substances than in those receiving only taurocholate (28.0 mg/g). Bile succinylsulfathiazole concentration was similarly reduced in rats given taurocholate simultaneously. Concomitant administration of either substance did not affect the binding of the other to plasma proteins. These results are consistent with the presence of a single liver-to-bile transport system for the 2 substances although they are in contrast to previous reports which showed an increase in biliary excretion of acidic compounds in animals given taurocholate. It is thus suggested that more than one transport system for biliary excretion of organic anions may exist.

2602 EXPERIMENTS WITH 1-^{14}C-ACETATE ON THE LIPID METABOLISM OF HUMAN LIVER BIOPSIES AND THEIR DEPENDENCE UPON THE DIETARY FAT CONTENT. *(Ger.)* Oette, K.; Phlippen, R.; Lanckohr, H. (Med. Clin., Cologne Univ., Germany). *Res. Exp. Med. (Berl.)* 162(2):83-103, 1974.

The lipid metabolism from 1-^{14}C-acetate and esterification was studied in human liver biopsies from patients with diseases other than liver cirrhosis. The patients were kept on special diets for 6 days prior to biopsy. The fatty acid synthesis and the esterification patterns of synthetized fatty acids were inversely dependent on the fat-carbohydrate content of the diet. By increasing the dietary fat content, fatty acid neosynthesis ceased almost completely at 55 cal%. The remaining activity was believed to be mainly due to chain elongation products. The activity of the enzyme system for fatty acid neosynthesis decreased slowly within 3 to 6 days. Most of the radioactivity appeared in the long-chain fatty acids with chain lengths over 16 carbon atoms. Fatty acids with not more than 10 carbon atoms accounted for 12% of the total activity. The rate of radioactivity uptake in the liver lipids was highest in normal diet, and lowest at dietary fat contents of 0-5 cal% and 55 cal%. The relative cholesterol content was substantially higher following fat-rich diet than after low-fat diet. The fatty acids synthesized at dietary fat contents ranging from 0 to 40 cal% were distributed rather evenly among glycerides and phosphatides. Low rate of synthesis in chronic hepatitis under low-fat diet was observed. The rate of 1-^{14}C-acetate incorporation in the total lipids with extremely reduced uptake in the phosphatides was measured in a patient with alcohol-induced fatty liver. The findings indicate that the composition of the liver glycerides is essentially determined by the acylase activities, and that 1-^{14}C-acetate tests are suitable for the determination of the suppression of the fatty acid neosynthesis in high-fat diet, which is practically complete at 50 cal% fat, but not for the study of the fatty acid neosynthesis in low-fat diet due to isotope dilution.

2603 PRODUCTION OF THE FEATURES OF REYE'S SYNDROME IN RATS WITH 4-PENTENOIC ACID. *(E.)* Glasgow, A. M.; Chase, H. P. (Univ. Colorado Med. Cent., Denver). *Pediatr. Res.* 9(3):133-138, 1975.

Male Sprague-Dawley rats were injected with pentenoic acid in an attempt to reproduce the features of Reye's syndrome. All rats given a single i.p. injection of 200 mg/kg purified pentenoic acid died within 1 hr. Mean plasma ammonia levels were elevated about 4-fold in rats allowed free access to food and about 6-fold in 2 of the 20-hr fasted rats following 200 mg/kg pentenoic acid. Fasted rats also responded with hypoglycemia and 3 rats developed mild acidosis. Chronic administration of pentenoic acid (50 mg/kg every 4 hr x 10, then 200 mg/kg i.p. once) resulted in slight weight loss, elevation of SGOT and blood urea nitrogen and decreased free fatty acid levels but no change in blood glucose, Na^{+} or total bilirubin. Livers from treated rats showed extensive fatty degeneration but no evidence of necrosis, inflammation or bile stasis. It is concluded that pentenoic acid, an analog of hypoglycin, produces findings similar to those of Reye's syndrome and to Jamaican vomiting sickness.

2604 INFLUENCE OF HYDROCORTISONE ON BLOOD CLOTTING AND FIBRINOLYSIS AFTER A STANDARD RESECTION OF THE LIVER IN DOGS.

(E.) Hafstrom, L.; Lede, R.; Stehlin, J. S.; Brown, R. O. (St. Joseph Hosp., Houston, Tex.). *Surg. Gynecol. Obstet.* 139 (6):860-866, 1974.

Standard liver resection was carried out on 19 mongrel dogs. A group of 7 dogs was treated with hydrocortisone, 50 mg given before operation, 50 mg after, and 50 mg i.m. daily for 4 days. Another group of 7 dogs was given no hydrocortisone. A group of 5 dogs was also treated with hydrocortisone, 200 mg before and after the surgical procedure and 200 mg i.m. daily for 4 days after the operation. Three dogs were subjected to a sham procedure. Blood samples were taken before and after resection, and used for the tests on blood coagulation and fibrinolysis. There was no difference in blood clotting and fibrinolysis between the group treated with 50 mg hydrocortisone and the untreated group. Of the 14 dogs in these 2 groups, 6 had a prolonged activated partial thromboplastin time on the day of resection and 2 the day after the resection. On the other hand, none of the 5 dogs given 200 mg hydrocortisone had a prolonged activated partial thromboplastin time. The causes of the prolonged activated partial thromboplastin time after hepatic resection were decreased synthesis, increased fibrinolysis without consumption, release of anticoagulative factors, and local or general intravascular coagulation. Evidence of inhibitory substances was found in 3 dogs. There was no effect of hydrocortisone on the post-operative mortality rate after liver resection. These results suggest that large doses of hydrocortisone before and after resection can prevent a prolongation of activated partial thromboplastin time after resection but the possible negative effects of hydrocortisone on the regenerative process and on metabolism should be considered.

2605 RAPID TRANSESTERIFICATION OF BILIRUBIN GLUCURONIDES IN METHANOL.

(E.) Salmon, M.; Fenselau, C.; Cukier, J. O.; Odell, G. B. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *Life Sci.* 15(12):2069-2078, 1974.

The rapid transesterification of bilirubin conjugates exposed to methanol was studied. Rat bile, washed with hexane and chloroform and lyophilized, was separated on thin layer chromatography into two major components. Glucuronic acid and bilirubin were present in the faster moving spot in a molar ratio of 0.96:1, and in the slower in a 2.01:1 ratio. Conversion of the slow running spot to sulfanilyazo derivatives yielded one class of derivatives on cellulose and silica gel plates suggesting that the two halves of the bilirubin molecule are identically conjugated. The faster spot was converted to two classes of sulfanilylazo derivatives separable by thin layer chromatography, suggesting that only half of the tetrapyrrole is conjugated. Based on these and further analyses, the two major components of the washed bile were identified as the mono- and diglucuronide conjugates of bilirubin. Characterization of the transesterification products formed after solution in methanol for 2 hr revealed dimethyl and monomethyl bilirubin. The conjugates of bilirubin and their methyl esters were isolated by thin layer chromatography and the isolates were chemically quantitated for their bilirubin and glucuronic acid composition. Characterization of the bilirubin methyl esters was performed by mass spectrometric analysis of the trimethylsilyl and phenylazo derivatives. Additional confirmation of the assignment of the dimethyl diester structure to the major product of transesterification by methanol was obtained by comparison to the authentic dimethyl diester of bilirubin. Ultraviolet absorption curves were identical and mass spectra were similar with very small molecular ion peaks at m/e 612 and major peaks at m/e 227, 241, 300, and 313. These results are significant in understanding hepatic excretion of bilirubin. Solvent partitioning of polar conjugates of bilirubin in bile have frequently employed methanol and chloroform. Because of the *in vitro* capacity of glucuronides of bilirubin to undergo transesterification in methanol, the resulting methyl esters would be preferentially recovered in the apolar chloroform layer. Subsequent chemical analysis by diazo reaction would lead to both a qualitatively and quantitatively erroneous interpretation of the excretion of unconjugated bilirubin in bile, as the methyl esters of bilirubin have the same reaction requirements as unconjugated bilirubin with diazotized sulfanilic acid, ethyl anthranilate and phenyl diazonium chloride. Such transesterification may contribute to differences noted by workers in the amounts of free, mono-, and diglucuronides of bilirubin recovered in bile. This reaction offers an alternative to transamination for the characterization of conjugates of bilirubin.

2606 KINETIC PROPERTIES OF BABOON LIVER ALKALINE PHOSPHATASE.

(E.) Balinsky, D.; Hammond, K. D.; Bershon, I.; Jersky, J. (South African Inst. Med. Res., Johannesburg). *S. Afr. J. Sci.* 70(2):61-62, 1974.

The kinetic properties of alkaline phosphatase purified from the livers of baboons were studied following auxiliary liver transplant. Michaelis constants for p-nitro-phenylphosphate at pH 9.0 and 10.2 and for phenolphthalein monophosphate at pH 9.9 were 0.044, 0.44 and 2.71 mM, resp. Enzyme activity was inhibited by ethylenediaminetetraacetic acid, L-cysteine and L-histidine and was stimulated by Mg^{++} ions. In addition, several other amino acids exhibited uncompetitive inhibition possibly by inhibiting breakdown of the phosphoryl-enzyme complex. Isoelectric focusing in polyacrylamide gels showed an isoelectric point of pH 4.3-4.6. The enzyme showed 50% inactivation at 58 C after 32 min. These properties were similar to those of human alkaline phosphatase with the exception of thermostability and isoelectric point.

2607 ACETAMINOPHEN-INDUCED HEPATIC NECROSIS. V. CORRELATION OF HEPATIC NECROSIS, COVALENT BINDING AND GLUTATHIONE DEPLETION IN HAMSTERS.

(E.) Potter, W. Z.; Thorgeirsson, S. S.; Jollow, D. J.; Mitchell, J. R. (Lab. Chem. Pharmacol., Natl. Inst. Health, Bethesda, Md.). *Pharmacology* 12(3): 129-143, 1974.

The relationships between hepatic glutathione depletion, arylation of hepatic macromolecules *in vivo* and *in vitro* and hepatic necrosis were studied after administration of acetaminophen to hamsters. Animals treated with 3-methylcholanthrene (40 mg/kg i.p.) for 3 days followed by acetaminophen (150-300 mg/kg) 24 hr later showed an increase in incidence and severity of liver necrosis. Treatment with phenobarbital (75 mg/kg), piperonyl butoxide (0.8 ml/kg), and cobaltous chloride (50 mg/kg) followed by acetaminophen (300-425 mg/kg) caused a decrease in incidence and severity of liver necrosis. Diethyl maleate (0.4 ml) was administered to deplete endogenous hepatic glutathione followed 30 min later with acetaminophen (200-425 mg/kg); both the severity of necrosis and mortality rate increased. None of the pretreatments appeared to alter absorption of acetaminophen, but piperonyl butoxide decreased its rate of disappearance in plasma, phenobarbital increased its rate of disappearance, and 3-methylcholanthrene had little effect on its plasma concentration. When ^{3}H-acetaminophen (300 mg/kg) was used, the amount of covalently bound metabolites of acetaminophen found in the liver paralleled the severity of the liver necrosis. Covalent binding of radiolabel to hamster microsomes was dependent on NADPH and O_2 and inhibited by a specific antibody against purified NADPH cytochrome c reductase. In hamsters pretreated with 3-methylcholanthrene, hepatic concentration of glutathione was depleted to 10% of normal 75 min after acetominophen. Piperonyl butoxide markedly decreased and phenobarbital moderately decreased the glutathione depletion. The results support the hypothesis that acetaminophen-induced hepatic necrosis results from the metabolic activation of the drug to an arylating metabolite by cytochrome P-450 oxidases in the liver.

2608 EFFECT OF COLCHICINE ON COLLAGEN, ALBUMIN AND TRANSFERRIN SYNTHESIS BY CIRRHOTIC RAT LIVER SLICES.

(E.) Rojkind, M.; Kershenobich, D. (Cent. Invest. Adv. Stud., Natl. Polytech. Inst., Mexico City, Mexico). *Biochim. Biophys. Acta* 378(3): 415-523, 1975.

The effect of colchicine and L-azetidine-2-carboxylic acid on liver function and collagen synthesis was studied in rats made cirrhotic by the chronic administration of CCl_4 (0.15 ml i.p. 3/week, 20 injections). The control group of rats was killed 24-48 hr after the last dose of CCl_4; the second group kept 30 days without further treatment; the third group treated with colchicine (10 μg/day intragastrically 5/week, 20 injections); the fourth group was treated with 10 μM L-azetidine-2-carboxylic acip p.o. every other day for 12 doses. Histological examinations of the liver were made and the *in vitro* incorporation of ^{14}C-labeled proline into collagen and non-collagenous proteins was analyzed, and its incorporation into albumin and transferrin. Liver function in rats receiving CCl_4 was impaired as evidenced by high values of serum albumin; incorporation of radioactive proline into collagen hydroxyproline was greatly enhanced. In animals treated with colchicine, a 50% inhibition in proline incorporation into collagen hydroxyproline was observed and the amount of conjugated bilirubin was 0.49 mg/100 ml. Transferrin biosynthesis remained constant in both cirrhotic and colchicine liver slices. Rats treated with L-azetidine-2-carboxylic acid during the 30-day period following CCl_4 showed a slight but not significant improvement in liver function; collagen synthesis and extent of fibrosis were similar to controls. The results show that the administration of colchicine to cirrhotic animals was accompanied by an improvement in liver function; thus, colchicine may be clinically useful in treating human patients with liver cirrhosis.

2609 TRANSIENT LIQUID CRYSTALS IN HUMAN BILE ANALOGUES.

(E.) Holzbach, R. T.; Marsh, M. (Cleveland Clin. Found., Ohio). *Mol. Cryst. Liquid Cryst.* 28(2):217-222, 1974.

The process of phase transition and equilibration was studied by phase separation microscopy in 30 bile analog systems differing in relative lecithin:bile salt concentrations. Although not observed in the systems in which lecithin concentration was less than 14%, those with lecithin concentrations between 14-30 M% developed a liquid crystalline mesophase which gradually developed into cholesterol microcrystallites. The transition times for development of the cholesterol crystals were a function of the lecithin concentration, ranging from 7 days for 14-18 M% to 21 days for 22-30 M%. Solutions containing lecithin from 35-65 M%, concentrations which exceed that allowing for maximum cholesterol solubility, remained turbid due to a persistent mesophase. Fresh human bile specimens from patients with gallstones, which contained more cholesterol crystals than specimens from normal subjects, underwent spontaneous transition phenomena identical to those seen in the compositionally similar bile analog solutions. It is concluded that a transient crystalline mesophase observed in human bile is seen in physiologically relevant lipid concentrations.

2610 EFFECT OF BILIARY STASIS AND HEPATOTOXINS ON THE EXCRETION OF IOPANOATE IN THE RAT.

(E.) Cooke, W. J.; Berndt, W. O.; Mudge, G. H. (Dartmouth Med. Sch., Hanover, N.H.). *J. Pharmacol. Exp. Ther.* 192(3):618-629, 1975.

The renal and biliary excretion of the cholecystographic compound iopanoic acid was analyzed in male Sprague-Dawley rats in the presence of hepatic dysfunction induced with several agents and after biliary obstruction produced surgically. Hepatic dysfunction was induced with CCl (1 or 2 mg in corn oil p.o., 18 or 20 hr prior to the experiment, SKF 525-A (25 mg/kg i.v. 30 min prior to iopanoate administration), taurolithocholic acid (5 mg/ml in 0.15 M NaCl containing 10% bovine serum albumin in an infusion started 30 min before and completed 15 min after iopanoate injection, and d-napthyliosthiocyanate (100 mg/kg in 1.5% carboxymethylcellulose p.o. 18 or 20 hr prior to the experiment) and by acute and chronic surgical ligation of the bile duct. Biliary and urinary excretion of ^{125}I-labeled iopanoate was measured after a total dose of iopanoate of 5 mg/kg was given i.v. over a 2-min period. In the absence of normal biliary excretion, the amount of iopanoate excreted in the urine varied from 0.25-11.2% of the dose, with highest rates of urinary excretion occurring after α-naphthylisothiocyanate and chronic stasis. Drug disposition was further determined by tissue analysis of liver and kidney. The results indicate that, for a drug that is normally almost exclusively excreted by the bile, in the presence of hepatic dysfunction the amount excreted by the alternate route depends on the type of the induced hepatic disorder. It is concluded that the intrarenal distribution of ^{125}I-radioactivity is strongly influenced by its plasma concentration rather than just by the rate of excretion in the urine.

2611 BIOSYNTHESIS OF BILE ACIDS IN MAN. HYDROXYLATION OF THE C_{27}-STEROID SIDE CHAIN.

(E.) Bjorkhem, I.; Gustafsson, J.; Johansson, G.; Persson, B. (Dep. Chem., Karolinska Inst., Stockholm, Sweden). *J. Clin. Invest.* 55:478-486, 1975.

The mechanisms of side chain degradation in the biosynthesis of bile acids in man were studied by analyzing hydroxylations of the side chain of different C_{27}-steroids catalyzed by the mitochondrial and microsomal fractions of liver homogenates from 14 patients with various disease (cholelithiasis, 1; carcinoma of the pancreas, 1; carcinoma of the stomach, 2; chronic myelocytic leukemia, 2; Hodgkin's disease, 2; agranulocytosis, 1; hereditary spherocytosis, 1; pheochromocytoma, 1; lymphosarcoma, 1; intoxication with tricyclic antidepressants, 1; and head injury, 1). Liver tissues were homogenized within 5-30 min after excision of the sample. The microsomal fraction was obtained from the homogenate by centrifugation at 800 g, 20,000 g and 100,000 g. The microsomal pellet was resuspended in the homogenizing medium and homogenized before incubation. The mitochondrial fraction was obtained by resuspension in 0.25 M sucrose of the pellet obtained after centrifugation at 20,000 g and recentrifugation at 8500 g for 12 min. In standard incubations with the microsomal fractions, 250 μg of the steroid, dissolved in 50 μl of acetone, was incubated with 1.5 ml of the microsomal fraction in a total volume of 3 ml of the homogenizing medium. In standard incubations with the mitochondrial fraction, 100 μg of the steroid dissolved in 50 μl of acetone was incubated with 1.0 ml of the mitochondrial fraction in a total volume of 3 ml of the homogenizing medium. Incubations were performed at 37 C for 20 min and were terminated by the addition of 20 vol of chloroform-methanol. The chloroform extract was evaporated and subjected to thin-layer chromatography. The microsomal fraction catalyzed an efficient 25-hydroxylation of 5 β-cholestane-3α, 7α, 12α-triol. A small extent of 23-, 24-, and 26-hydroxylation of the same substrate was observed. 5 β-cholestane-3α, 7α-diol was hydroxylated in the 25-position only to a very small extent. The mitochondrial fraction catalyzed 26-hydroxylation of cholesterol, 5-cholestene-3β, 7α-diol, 5β-cholestane-3α, 7α-diol, 7α-hydroxy-4-cholesten-3-one, and 5β-cholestane-3α,7α,12α-triol. Addition of Mg^{++} stimulated the 26-hydroxylation of cholesterol but had no effect or an inhibitory effect on 26-hydroxylation of the other substrates, indicating a heterogeneity of the mitochondrial 26-hydroxylating system. The level of 26-hydroxylase activity towards different substrates varied considerably with different mitochondrial preparations. The results indicate that microsomal 26-hydroxylation is less important than mitochondrial 26-hydroxylation under normal conditions; the possibility that microsomal 25-hydroxylation is important cannot be ruled out.

2612 ACETAMINOPHEN-INDUCED HEPATIC NECROSIS. VI. METABOLIC DISPOSITION OF TOXIC AND NONTOXIC DOSES OF ACETAMINOPHEN.

(E.) Jollow, D. J.; Thorgiersson, S. S.; Potter, W. Z.; Hashimoto, M.; Mitchell, J. R. (Natl. Heart Lung Inst., Bethesda, Md.). *Pharmacology* 12(4/5):251-271, 1974.

The relation between the metabolic disposition of acetaminophen and the susceptibility of male golden Syrian hamsters, male GP mice, and male Sprague-Dawley rats to acetaminophen-induced liver necrosis was examined. Animals were allowed food and water *ad libitum*. Some were treated daily with i.p. doses of phenobarbital (80 mg/kg for 3 days) or 3-methylcholanthrene (20 mg/kg for 2 days). Other animals received piperonyl butoxide (hamsters, 800 mg/kg, mice 1360 mg/kg, and rats 800 mg/kg) i.p. 30 min before acetaminophen. Animals received various doses of acetaminophen (25-1200 mg/kg i.p.) dissolved in 0.9% saline solution. ^{3}H-acetaminophen was added to the dose so that each animal received 100 μCi/kg. Metabolites of acetaminophen excreted in the urine were separated by thin layer chromatography and identified by mass spectrometry. The fraction of low doses of acetaminophen converted to the mercapturic acid metabolite was highest in the most susceptible species (hamster, mice) and lowest in the more resistant species (rat). Pretreatment regimens known to potentiate the hepatotoxicity of acetaminophen increased mercapturic acid formation whereas treatments which protect from liver damage decreased mercapturic acid formation. The data suggest that the activity of the mercapturic acid-forming pathway *in vivo* reflects the activity of the hepatotoxic pathway. As the dose of acetominophen was increased to hepatotoxic levels, the fraction of the dose excreted as the mercapturic acid decreased markedly, commensurate with the known depletion of hepatic glutathione under these conditions. It is suggested that the normal metabolic intermediate which conjugates with glutathione in the mercapturic acid pathway is also the electrophilic metabolite which in the absence of glutathione arylates hepatic macromolecules and causes cell death.

2613 EFFECTS OF CHRONIC INGESTION OF SOME LOWER ALIPHATIC ALCOHOLS IN RATS.

(E.) Hillblom, M. E.; Franssila, K.; Forsander, O. A. (Res. Lab. State Alcohol Monop., Helsinki, Finland). *Res. Commun. Chem. Pathol. Pharmacol.* 9(1):177-180, 1974.

The possibility that n-propanol or isobutanol may be more toxic than ethanol was tested by giving diluted (1 M) solutions of ethanol, n-propanol, or isobutanol to 4-month old male Wistar rats for their sole drinking fluid for 4 months. Ordinary laboratory chow containing about 26% of the calories as protein, 55% as carbohydrate, and 19% as fat was provided *ad libitum*. At the end of the test period the animals were decapitated and their livers weighed. Formalin-fixed liver secretions were stained with hematoxylin and eosin, toluidine blue, the periodic acid Schiff reaction with and without diastase, and Weigert-van Gieson, and evaluated under a light microscope. The amounts of ethanol and n-propanol consumed remained almost constant from beginning to end of the experiment, but the consumption of isobutanol increased significantly. A lower ratio of weight gain to caloric intake was seen in the rats given n-propanol indicating that this group utilized food less efficiently than the ethanol-treated group. The mechanism by which n-propanol interferes with food utilization is unknown. Rats treated with isobutanol had enlarged gas- and/or food-filled stomachs, and some animals had signs of small intestinal bleeding and constipation. Since the increase in isobutanol consumption was accompanied by slight increases in total caloric and fluid intakes, it is speculated that isobutanol somehow disturbed food absorption from the gastrointestinal tract. The absence of liver abnormalities in the ethanol-treated animals is attributed to the fact that the amount of ethanol consumed was not enough to produce fatty, cirrhotic, or fibrotic lesions in the liver. It is suggested that n-propanol and isobutanol are not more harmful to the rat liver than ethanol when administered p.o. for periods of several weeks to several months. The daily doses of congeners in this animal experiment greatly exceeded those generally consumed in hard liquors and wine by heavy drinkers. The duration of exposure, however, was much shorter. No extrapolation, therefore, to the situation in man can be made and the relative hepatotoxicity of the main congeners as compared to ethanol in humans remains unresolved.

2614 INFLUENCE OF PRIMARY BILE ACID FEEDING ON CHOLESTEROL METABOLISM AND HEPATIC FUNCTION IN THE RHESUS MONKEY.

(E.) Webster, K. H.; Lancaster, M. C.; Hofmann, A. F.; Wease, D. F.; Baggenstoss, A. H. (VA Hosp., Alburquerque, N.M.). *Mayo Clin. Proc.* 50(3):134-138, 1975.

Studies were performed to define the effect of feeding cholic acid or chenodeoxycholic acid (in doses similar to those used for gallstone therapy in man) on cholesterol metabolism, liver function, and liver morphology in the rhesus monkey. After a 5-week equilibration period, 4 of 10 monkeys were killed for bile collection and the remaining 6 used for the metabolic study. Labeled cholesterol was given i.v., and cholesterol pool size and turnover rates were determined by an isotope dilution technique for the 10-week study period. After these initial studies, 3 animals received chenodeoxycholic acid p.o. (both 20 mg/kg/day) for an additional 15 weeks. In the monkeys fed chenodeoxycholic acid, there was no consistent increase in the total exchangeable cholesterol pool or input to the cholesterol pool. In the 3 monkeys fed cholic acid, the total exchangeable pool increased in all animals and input to the cholesterol pool increased in 2. SGPT increased transiently in 2 animals in each group. Morphologic abnormalities (triaditis with atypical ductular proliferation) were noted in 1 animal; this animal was ingesting chenodeoxycholic acid but had normal liver test results at the time of biopsy. Biliary bile acids contained 8-14% lithocholic acid in the chenodeoxycholic acid group and 48-72% deoxycholic acid in the cholic acid group. The present study is the third to show that chenodeoxycholic acid administration does not expand the exchangeable cholesterol pool or increase serum cholesterol levels in primates, including man. During bile acid feeding, the ratio of secondary to primary bile acids is greater in the rhesus monkey than in gallstone patients. The reason for the increased proportion of secondary bile acid is unknown. The simplest explanation is that increased input of 7 α-dehydroxylated bile acids occurs in the monkey, presumably in the cecum. It is also possible that intestinal conservation may be more efficient in the monkey. Chenodeoxycholic acid appears to be less hepatotoxic in man than in the rhesus monkey. Whether the hepatotoxicity is caused by increased lithocholate input of altered lithocholate disposition is unclear. It is also not clear whether these findings are invariably true in the rhesus monkey or merely reflect an abnormality in the intestinal flora of the 3 animals used in this study.

2615 ASPECTS OF BILE SECRETION IN THE RABBIT.

(E.) Rutishauser, S. C. B.; Stone, S. L. (Dep. Physiol., Univ. Coll., Cardiff, Wales). *J. Physiol. (Lond.)* 245(3):567-582, 1975.

The effects of a dihydroxy and a trihydroxy bile salt were compared in anesthetized rabbits in which hepatic bile was collected by cannulation of the common bile duct. The animals were anesthetized either with pentobarbitone (30 mg/kg in 0.9% NaCl injected into an ear vein) or with urethane (5 ml/kg of a 25% solution i.p.). Bile flow in the group anesthetized with urethane was significantly lower than that in the group anesthetized with pentobarbitone sodium. The concentration of bile salt in bile was significantly higher in the urethane group; this was associated with a higher biliary osmolality. I.p. injection of a hypertonic solution of sucrose (3 M) decreased bile flow and produced changes in the ionic composition of bile and of plasma. The biliary concentrations of sodium, potassium and bicarbonate all increased despite the fact that the plasma concentrations of these ions declined. The infusion of sodium taurodeoxycholate (1.5 - 20 μM/min i.v.) gave higher rates of bile flow than did equimolar infusions of sodium taurocholate, and unlike taurocholate, increased the bicarbonate concentration of bile. The choleretic efficiency of taurodeoxycholate decreased from about 50 ml/mM at an infusion rate of 20 nm/min/g liver to about 15 ml/mM at an infusion rate of 200 nM/min/g liver. On no occasion did the infusion of bile salt increase the osmolality of bile or of plasma. Both taurodeoxycholate and taurocholate increased the concentrations of sodium and bile salt in bile, and decreased the concentration of chloride. Taurodeoxycholate consistently increased the concentration of bicarbonate in bile, whereas taurocholate caused a net decrease in concentration. Acetazolamide (10-100 mg/kg) increased the concentration of bicarbonate both in bile and in plasma, and had little effect on bile flow. The infusion of BSP (5 mg/kg i.v.) decreased the excretion of bicarbonate into bile, and was associated with the formation of a hypotonic bile. It is concluded that the three anions studied, taurodeoxycholate, taurocholate, and BSP, differ in the effects that they have on the flow and composition of bile. If the anions differ in this way, then the factors limiting their secretion into bile may not be simply the availability of carrier site at the biliary membrane, but may be the prevailing conditions within the canaliculus itself.

2616 THE CHOLERETIC EFFECT OF IODIPAMIDE. *(E.)*

Feld, G. K.; Loeb, P. M.; Berk, R. N.; Wheeler, H. O. (Univ. California, San Diego, Sch. Med., La Jolla). *J. Clin. Invest.* 55:528-535, 1975.

Experiments were performed in 3 trained, unanesthetized dogs (prepared several months earlier by cholecystectomy and insertion of a Thomas cannula into the duodenum opposite the major duodenal papilla) to determine if the increased bile flow produced by the radiographic contrast medium, iodipamide, is canalicular or ductular in origin, to quantitate the choleresis associated with iodipamide and taurocholate excretion, and to correlate these findings with the results of *in vitro* studies in which the osmotic activities of iodipamide and taurocholate in both isotonic saline and bile were determined. A priming injection of 2.5 μCi of [^{14}C]erythritol dissolved in 70% ethanol was given, followed by a continuous infusion of 0.025 μCi/min. Two experiments were performed in each dog by infusion of a 15.3% solution of methylglucamine iodipamide in a stepwise fashion at 7 rates increasing from 0.33 to 7.33 μM/min/kg. Bile samples were collected at each infusion rate after bile flow had been stable for at least 30 min. Blood samples were collected at the midpoint of each bile collection period. In 2 additional studies, iodipamide was infused at the relatively low rate of 1.0 μM/min/kg. In these investigations iodine and [^{14}C]erythritol concentrations were measured in plasma and bile. In another experiment, a 1.5% solution of sodium taurocholate in distilled water was infused in a stepwise fashion at 4 rates increasing from 0.5 to 3.0 μM/min/kg in each of 2 dogs. Iodine and bile salt concentrations were measured in bile. The plasma erythritol clearance increased linearly with the excretion of iodipamide, indicating that iodipamide stimulates canalicular bile flow. The plasma erythritol clearance increased linearly with the excretion of iodipamide, indicating that iodipamide stimulates canalicular bile flow. The choleretic potency of iodipamide (22 ml/mM) was approximately 3 times that of taurocholate (7.8 ml/mM), yet the osmotic activity of iodipamide in bile (1.5 mOsm/mM) was only twice as great as that of taurocholate in bile (0.8 mOsm/mM). The results suggest that per unit of effective osmotic solute secreted, iodipamide carries appreciably more water and diffusible solute into the bile canaliculi than does taurocholate. The reason for this difference is not apparent but possible reasons might include stimulation of active inorganic solute transport by iodipamide, alteration of canalicular membrane permeability by iodipamide, differences in electrical potential associated with transport of iodipamide and taurocholate, delayed reduction in the osmotic activity of iodipamide, and differences between the spatial distribution of the canalicular secretion of iodipamide and taurocholate.

2617 EFFECT OF DEOXYCHOLATE ON THE PEROXIDE OXIDATION OF LIPIDS IN LIVER MICROSOMES.

(E.) Mishin, V. M.; Lyakhovich, V. V. (Novosibirsk State Med. Inst., USSR). *Biofizika* 19(1):83-86, 1974.

The interdependence between the structural organization of rat liver microsomes modified with a detergent (deoxycholate) and the maximum rate of peroxide oxidation of lipids was investigated. The rat liver microsomes were isolated from a liver homogenate (1 part liver tissue to 2.5 parts of 0.25 M sucrose plus 0.01 M Tris HCl buffer, pH 7.4) by centrifuging for 60 min at 105,000 r.p.m., followed by reprecipitation. The rate of peroxide oxidation of lipids was determined polarographically from the uptake of O$_2$. Deoxycholate was added to the assay medium before the introduction of the microsomes. Treatment of the rat liver microsomes with deoxycholate at 0.115-0.9 mg/mg microsomal protein increased the activity of peroxide oxidation of lipids dependent on ascorbate. At the same concentrations of deoxycholate the rate of enzymatic peroxidation of lipids dependent on NADP-H did not change. In the presence of deoxycholate there was a fall in the degree of inhibition of peroxide oxidation of lipids by phenergan and ethylene diamine tetraacetate. It is concluded that the degree of integration of the microsomal membrane regulates the processes of peroxide oxidation of lipids. Treatment of the microsomes with deoxycholate apparently increases the binding of Fe^{+++} to the membrane, and, as a consequence, increases the number of radical-forming centers. Large amounts of deoxycholate (greater than 0.7-0.9 mg/mg of microsomal protein) suppress the peroxide oxidation of lipids both of enzymatic and non-enzymatic nature. This is explained by spatial separation of the centers of radical formation and the reaction substrates.

2618 EFFECTS OF PHENOBARBITAL UPON BILE ACID SYNTHESIS IN TWO STRAINS OF RATS. *(E.)*

Cohen, B. I.; Raicht, R. F.; Nicolau, G.; Mosbach, E. H. (Public Health Res. Inst. City New York, Inc., N.Y.). *Lipids* 10(3):168-174, 1975.

The effect of phenobarbital on cholesterol 7α-hydroxylase activity and bile acid output in Wistar and Sprague-Dawley rats was measured. In addition, the amount of biliary cholic acid was correlated with the microsomal 12α-hydroxylase activity in phenobarbital-treated rats. The rats were injected with sodium phenobarbital (100 mg/kg body weight/day) for 8 days. Fecal bile acid excretion was measured on days 6 and 8, and biliary bile acid composition, hepatic microsomal cholesterol, 7α-hydroxylase, and 7α-hydroxy-4-cholesten-3-one 12α-hydroxylase were determined at the end of the experiment. In the Wistar rat, injection of phenobarbital produced a doubling of fecal bile acid output (controls, 5.3 mg/rat/day; treated rats, 10.6 mg/rat/day) and a two- to threefold increase in cholesterol 7α-hydroxylase (13.5 pM 7α-hydroxycholesterol formed/mg protein/min in treated rats; 5.8 pM protein/min in the controls). The fecal bile acid output of Sprague-Dawley rats increased 20% in response to phenobarbital (controls, 9.5 mg/rat/day; treated rats, 11.6 mg/rat/day). The activity of cholesterol 7α-hydroxylase remained unchanged. In both strains, phenobarbital treatment produced a decrease in the proportion of cholic acid in total biliary bile acids (controls, 85%; treated groups, 65%). This was associated with an approximately 50% decrease of 7α-hydroxy-4-cholesten-3-one 12α-hydroxylase activity. Biliary cholesterol concentrations were reduced in phenobarbital-treated rats of both strains, but liver cholesterol concentrations remained unchanged. The drug produced an average 25% increase in liver weight. These findings confirm the previously published suggestion that phenobarbital is potentially useful in the treatment of gallstones since it produces a significant lowering of the relative cholesterol concentration in the bile in treated animals; biliary cholesterol concentrations of treated rats of both strains were decreased significantly. It is further suggested that the *in vitro* assay of cholesterol 7α-hydroxylase activity reflects the state of bile acid synthesis *in vivo* and that the *in vitro* activity of the microsomal 12α-hydroxylase reflects the proportion of cholic acid present in the bile.

2619 COMPARATIVE EFFECTS OF SODIUM TAURODEOXYCHOLATE AND SODIUM TAUROCHOLATE ON BILE SECRETION IN THE RAT, DOG AND RABBIT.

(E.) Rutishauser, S. C. B.; Stone, S. L. (Dep. Physiol., Univ. Coll., Cardiff, Wales). *J. Physiol. (Lond.)* 245(3): 583-598, 1975.

The biliary effects of sodium taurodeoxycholate and sodium taurocholate were investigated in anesthetized mongrel dogs and male Wistar rats, and in the isolated perfused rat liver and compared with previously determined effects in rabbits. Sodium taurocholate and sodium taurodeoxycholate were dissolved in 0.9% NaCl (2.0 μM/ml) and were infused i.v. into 7 dogs at rates ranging from 5-120 nM/min g liver. Both bile salts had similar quantitative and qualitative effects on the flow and composition of bile in the dog. The choleretic efficiency of sodium taurocholate was 8.5 ml/mM and that for sodium taurodeoxycholate was 9.6 ml/mM. The bile salts were dissolved in 0.9% NaCl (25-50 μM/ml) and were infused at rates ranging from 20-200 nM/min g liver into anesthetized rats. The bile salts had similar effects on the ionic composition of bile in the rat, but differed in that bile flow was not always directly related to the rate of bile salt secretion in bile, in the experiments with sodium taurodeoxycholate. Sodium taurodeoxycholate was hydroxylated to form sodium taurocholate by the liver of the rat but not by that of the dog. These findings indicate that sodium taurodeoxycholate is not a more efficient choleretic than sodium taurocholate in the rat or dog. This contrasts with the choleretic effects of this bile salt in the rabbit and suggests that sodium taurodeoxycholate is not inherently a good choleretic, but rather that it possesses special properties in the rabbit. It seems that deoxycholate, which is the major bile salt present in rabbit bile, has an important and individual role to play in the formation of bile in the species.

2620 INTERACTION BETWEEN ANTIPYRINE AND THE MICROSOMAL ETHANOL OXIDATION IN RAT LIVER.

(E.) Andreasen, P. B.; Bremmelgaard, A.; Larsen, B. K. (Rigs Hosp., Copenhagen, Denmark). *Pharmacology* 12(4/5):244-250, 1974.

The effect of antipyrine on the kinetics of ethanol oxidation in isolated microsomes from female Wistar rat livers was investigated. The rats were fasted 16 hr, anesthetized with ether, the liver removed and the microsomes prepared by ultracentrifugation. The microsomes were homogenized and the pooled microsomes from 2 rat livers used in each experiment. The incubation system contained 1.8 μM NADPH, 50 μM $MgCl_2$, 43 μM DL-isocitrate, 0.2 mg protein of isocitrate dehydrogenase, microsomal protein 1 mg/ml, and phosphate buffer pH 7.4 to a final volume of 5 ml. Antipyrine was added to obtain a concentration of 0.1 or 1.0 mM/liter. The mixture was preincubated for 5 min and the reaction started by addition of ethanol. Samples were drawn for analysis by gas chromatography at 0 and 10 min after the start of the reaction. The maximal elimination rate and the half saturation concentration were estimated from Lineweaver-Burk plots by linear regression. The average estimated maximal elimination rate for microsomal ethanol oxidation was 117.0 nM/min/g liver and half saturation concentration was 12.7 nM/liter ethanol. When corrections for microsomal losses during the preparation procedure are considered, the estimated average maximal elimination rate is 292.5 nM/min/g liver. The estimated maximal elimination rate and the half saturation concentration for microsomal ethanol oxidation in the presence of antipyrine at a concentration of 0.1 mM/liter were 123.9 nM/min/g liver. and 22.8 mM/liter, resp., and in the presence of antipyrine at a concentration of 1.0 mM/liter were 120.0 nM/min/g liver and 15.9 mM/liter, resp. There was no statistically significant change in maximal elimination rate and the half saturation concentration after the addition of antipyrine. The lack of effect of antipyrine on microsomal ethanol oxidation suggests that antipyrine and ethanol may be metabolized by different metabolic pathways in the hepatic microsomes.

2621 EFFECT OF BILE-DUCT LIGATION ON ORGANELLE MARKER ENZYMES IN THE LIVER AND SERUM OF RATS. *(E.)* Peters, T. J.; Neale, G.; Heath, J. R. (R. Postgrad. Med. Sch., London, England). *Clin. Sci. Mol. Med.* 48(4):307-313, 1975.

Sixteen marker enzymes for the principal subcellular organelles of rat liver were assayed in the liver of an inbred strain of male Wistar rats 1 day and 8 days after bile-duct ligation or after laparotomy as a control procedure; alterations in the activities of 8 of these enzymes in serum were also assessed. The microsomal enzymes in liver tissue showed complex changes. Benz[α]pyrene hydroxylase activity, predominantly found in the smooth endoplasmic reticulum, was decreased. Glucose 6-phosphatase activity and ribonucleic acid, which are localized predominantly in the rough endoplasmic reticulum, were increased. The plasma membrane enzyme alkaline phosphatase, increased in activity after bile-duct ligation. No changes in mitochondrial enzyme activities were noted after 1 day but there was a 50% reduction 8 days after ligation. Lysosomal enzyme activities did not change. Liver catalase and D-amino acid oxidase activities showed a slight increase at 1 day postligation but a significant fall by 8 days. Lactate dehydrogenase, a cytosol enzyme, showed a decrease in activity after 1 day but an increase in tissue activities 8 days after ligation. Serum activities of mitochondrial, plasma membrane, microsomal, lysosomal, and cytosol marker enzymes tended to increase postligation, particularly at 8 days. Monamine oxidase, a predominantly mitochondrial enzyme, was greatly elevated in the serum after 1 day but returned to normal levels in 8 days. These studies indicate that all the subcellular organelles of liver tissue are affected by bile duct obstruction. The results further indicate that ultrasensitive methods of enzyme analysis provide a useful tool for exploring subcellular changes in experimentally produced liver disease in animals.

2622 α-NAPTHYL-ISOTHIOCYANATE-INDUCED CHOLESTASIS IN THE RAT: STUDIES OF LIVER PLASMA MEMBRANE ENZYMES. *(E.)* Hertzog, P. J.; Bhathal, P. S.; Dorling, P. R.; LePage, R. N. (Dep. Pathol., Univ. Melbourne, Australia). *Pathology* 7(1):13-23, 1975.

A combined biochemical and morphological study was undertaken of acute α-naphthyl-isothiocyanate-induced cholestasis in female Sprague-Dawley rats. The rats were given a single p.o. dose (100 mg/kg body weight) of α-naphthyl-isothiocyanate in maize oil. Treated and control rats were killed 1, 2, 3, and 7 days after dosing, blood was collected, and liver removed immediately. Small pieces of liver were excised for morphological studies and the rest used for plasma membrane isolation. Conjugated and unconjugated serum bilirubin levels rose to a peak 2 days after treatment and returned to normal by 7 days. The conjugated fraction ranged from 60 to 80% of the total bilirubin levels at the times of maximum jaundice. The activities of 3 liver plasma membrane enzymes, Mg^{++}-ATPase, $(Na^{+}$-$K^{+})$-ATPase and 5'-nucleotidase, were significantly decreased at 2 days after treatment and returned to normal by day 7, thus varying inversely with the degree of hyperbilirubinemia. Enzyme histochemistry, used to demonstrate canalicular localization of Mg^{++}-ATPase in sections of whole liver and of isolated plasma membrane pellets showed that the reduction in activity was not a uniform partial loss, but represented a range of reductions in most canaliculi, a few remaining with normal staining intensity. Electron microscopic examination of liver sections in the first 3 days posttreatment showed dilatation of biliary canaliculi with almost complete loss of microvilli from most caniliculi and swelling of some of the remaining microvilli. Vesiculation of the endoplasmic reticulum with dissociation of ribosomes was also observed. It is suggested that after α-naphthyl-isothiocyanate intoxication there is a membrane lesion which may be responsible for the observed hyperbilirubinemia due to the failure of secretion of biliary constituents into the canaliculus. More direct studies are necessary, however, to determine whether any one of the enzymes is directly involved in the transport of biliary constituents across the bile canalicular membrane.

2623 ETHANOL METABOLISM IN THE VITAMIN C DEFICIENT GUINEA-PIG. *(E.)* Dow, J.; Goldberg, A. (Stobhill Gen. Hosp., Glasgow, Scotland). *Biochem. Pharmacol.* 24(8):863-866, 1975.

The effects of vitamin C deficiency and chronic ethanol treatment on the hepatic redox state and alcohol dehydrogenase activity was investigated in male albino guinea pigs. The guinea pigs were fed a vitamin C-deficient diet for 14 days. The ethanol pretreated groups were intubated daily with 2.5 g ethanol/kg body weight as a 50% solution. Redox state changes were investigated in guinea pigs that had been fasted overnight (18 hr) on the 14th day, injected i.p. with 1.5 g ethanol/kg body weight as 30% solution, killed 30 min later, and their livers rapidly removed. The rate of elimination of ethanol from the blood was determined in a separate but similarly treated group of animals in which 20 μl blood samples were removed from the ear vein at 1/2 hr intervals for 3 hr and blood ethanol measured by an internal standard gas-liquid chromatography method. Guinea pig liver microsomes were prepared from animals who received the standard treatment for 14 days but received no ethanol for 24 hr prior to sacrifice. Aniline hydroxylase, cytochrome P-450, cytochrome b_5, microsomal ethanol oxidizing system activity, NADPH oxidase activity, catalase activity, alcohol dehydrogenase activity and ascorbic acid levels were measured in the microsomal preparations. There was a small but significant decrease in the redox state shift with ethanol in both the ethanol pretreated normal and scorbutic animals compared with the untreated controls. No difference in terminal body weight, liver weight, liver/body weight or alcohol dehydrogenase activity was found between any of the groups of animals studied. The liver ascorbic acid content was decreased to 30% of normal values in both the vitamin C-deficient and chronic ethanol treated vitamin C-deficient groups. Microsomal aniline hydroxylase and NADPH oxidase activities were reduced in the vitamin C-deficient groups and the amount of cytochrome P-450 was decreased but there was no change in the *in vivo* rate of ethanol elimination or in the concentration of cytochrome b_5. Chronic ethanol treatment did not induce microsomal enzyme activities or increase the concentration of microsomal electron transport components. No evidence was found for a role *in vivo* for the microsomal ethanol oxidizing system in ethanol metabolism, as a reduction in microsomal enzyme activities and electron transport components had no effect on ethanol elimination *in vivo*. When alcohol dehydrogenase activity is normal, no further systems appear to be required for ethanol metabolism.

2624 REGULATION OF HEPATIC REGENERATION IN RATS BY SYNERGISTIC ACTION OF INSULIN AND GLUCAGON.

(E.) Bucher, N. L. R.; Swaffield, M. N. (Massachusetts Gen. Hosp., Boston). *Proc. Natl. Acad. Sci. USA* 72(3):1157-1160, 1975.

The function of the pancreatic hormones in hepatic regeneration was examined in eviscerated male Sprague-Dawley rats. The rats were subjected to resection of the gastrointestinal tract, pancreas, and spleen, and maintained by continuous i.v. infusion. Such animals, receiving only electrolytes and glucose, responded to 68% hepatectomy with a significant rise in hepatic DNA synthesis, which was, however, greatly delayed and diminished compared with normal controls. The activity was restored to normal by infusion of insulin and glucagon (supplemented with glucose and amino acids) but not by either hormone alone; it was not decreased by delaying the start of hormone treatment for 6-7 hr after partial hepatectomy. Infusion of insulin and glucagon into rats with intact livers did not appreciably elevate DNA synthesis. In normal rats partial hepatectomy was followed by an abrupt fall in portal vein insulin concentration. These findings suggest that agents other than insulin and glucagon may serve to initiate hepatic regeneration, but that these 2 hormones acting synergistically are major regulators of the rate and perhaps also the extent of the regenerative process.

2625 EFFECT OF LONG-TERM ADMINISTRATION OF DIFFERENT ALCOHOLIC BEVERAGES TO RATS ON LIVER LIPID METABOLISM AND BILE ACID CONJUGATION.

(E.) Jordo, L.; Olsson, R.; Schersten, T. (Dep. Med., Univ. Goteborg, Sweden). *Digestion* 11(3/4):183-193, 1974.

The effect of various alcoholic beverages (ethanol, brandy, whisky, gin and red wine of cheap qualities) on hepatic triglyceride, phospholipid, and cholesterol concentration, incorporation rate of glycerol into hepatic triglycerides and phospholipids, and bile acid conjugation rate was studied in male Sprague-Dawley rats fed alcohol as 50% of the caloric intake for 8-9 months. Two groups of rats served as controls: one fed glucose instead of alcohol and another fed a standard laboratory diet. A special series of rats fed the same amount of ethanol for 10 days was also investigated. The mean daily food consumption, which was initially about 380 kcal/kg, decreased with the growth of the animals to about 160 kcal/kg toward the end of the experiments. Thus the mean daily alcohol consumption over the whole period was about 20 g/day. Serum ethanol concentrations, measured in 15 animals at different times of the day during the last 2 months, ranged between 55-270 mg/100 ml. In the long-term study no unambiguous changes of hepatic lipid concentration, incorporation rate of glycerol into hepatic lipids, and bile acid conjugation rate were found in the glucose-fed animals. In the 10-day study the ethanol-fed rats showed a 60% increase of hepatic triglyceride concentration and of the incorporation rate of glycerol into hepatic triglycerides as well as 30% increase of the rate of bile acid conjugation compared with glucose-fed controls. The various alcoholic beverages showed almost no differences in their effects on lipid metabolism or bile acid conjugation rate. The results suggest that other pathways for ethanol metabolism than the NADH_2-producing alcohol dehydrogenase system become of increased importance with prolonged ethanol administration. In agreement with other studies of similar duration, in which fat constituted less than 20% of the total calories, a persistant steatosis was not found after 8-9 months of ethanol feeding. It is suggested therefore, that ethanol *per se* does not cause persistant fatty liver but that a concomitant high fat intake might be one key factor for a progressive and/or persistent steatosis.

2626 PORTACAVAL SHUNT IN THE RAT: TECHNIQUE AND RESULTS.

(Ger.) Zelde, O.; Schmitt, C. G. (Surg. Clin., Univ. Marburg/Lahn, Germany). *Z. Gastroenterol.* 12(3):193-200, 1974.

A comparison was made of portacaval shunts with end-to-side and side-to-side anastomoses in male SIV 50 rats. Controls consisted of rats which underwent sham surgery, i.e. the hepatic artery was mobilized from the portal vein. Rats were sacrificed either 21 days or 6 months after surgery, and the condition of the anastomosis was studied by splenoportography. The postoperative mortality was 0% for functional end-to-side and side-to-side anastomoses. By 3 months after surgery, 60% of the rats with end-to-side anastomoses had died and by 6 months, 87%. The corresponding mortality rates for rats with side-to-side anastomoses were 33% and 40%, resp. This suggests that not all blood from the portal vein bypasses the liver in side-to-side anastomoses. Body weights were significantly decreased 6 months after end-to-side anastomoses, but not after side-to-side anastomoses or sham surgery. In rats with end-to-side anastomoses, the weight of the liver decreased to a greater extent during the first 21 days after surgery than in the other groups of animals; no appreciable change in the weight of the liver occurred thereafter. Histological examination of the liver of rats that died revealed moderate steatosis, cell atrophy, occasional pyknosis and vacuolization of the nuclei and, in some cases, small areas of necrosis. No small scars were found in the hepatic parenchyma which would indicate prior necrosis. On the basis of these findings, portacaval shunts with side-to-side anastomoses are recommended for use as an animal model in patho-physiological investigations since the animals can be followed for a relatively long time after surgery.

2627 THE ROLE OF SEX DIFFERENCES IN THE EFFECT OF ANABOLICS ON THE LIVER. *(E.)* Kulcsar-Gergely, J.; Kulcsar, A.; Kiss, A. (Univ. Med. Sch., Debrecen, Hungary). *Arzneim. Forsch.* 25(3):417-420, 1975.

Two anabolic steroids, nandrolone phenpropionate and nandrolone decanoate, were studied in Wistar rats to determine whether they had any influence on the course of a given liver function and caused any enzyme induction; whether there were any sex differences when exerting their influence; and, when administered simultaneously with carbon tetrachloride (1.0 ml/kg 3 times a week), how they influenced the severity of the induced liver lesion. Both steroids were administered i.m. in oil injection, a single dose being 25 mg/kg. In continuous treatment the animals were injected 3 times a week. Body weight, wet liver weight, and the protein content of liver homogenates increased under the effect of anabolic treatment. The largest increases were seen in females treated with nandrolone phenpropionate. Hepatic hexobarbital metabolism, measured *in vivo*, was increased by a single dose of anabolic. The prolongation of treatment kept shortening hexobarbital anesthesia in females only. Even 8 weeks after the end of treatment the effect was invariably seen in females but not in males. There was no decline in ovarian function. The hepatotropic effect of anabolic treatment, given simultaneously with carbon tetrachloride, was demonstrated in females. Under the effect of anabolic treatment, hepatic hexobarbital metabolism, which had been impaired by the experimental lesion, remained near the levels of the untreated animals. Previous observations that the ability of steroids to cause enzymatic induction is related to their anabolic character are supported by these findings. Induction was stronger and more long-lasting in females than in males. According to comparative analyses of the effect on the liver, nandrolone phenpropionate is more effective, as the same dose had double the effect of nandrolone decanoate. It is concluded that the effect of anabolics on enzymatic induction may be of therapeutic value when carefully chosen preparations are applied in adequately selected cases and sex differences as well as the kind of liver damage are taken into account.

2628 THE SUBCELLULAR LOCALIZATION OF ALDEHYDE DEHYDROGENASE IN RAT LIVER. *(E.)* Horton, A. A.; Barrett, M. C. (Dep. Biochem., Univ Birmingham, England). *Arch. Biochem. Biophys.* 167(2):426-436, 1975.

Evidence supporting the existence of 3 aldehyde dehydrogenases, betaine aldehyde dehydrogenase and 2 aldehyde dehydrogenases ALDH-I and ALDH-II, in female Wistar rats was confirmed and the localization of these enzymes within the liver cell investigated by extensive subcellular fractionation studies. The subcellular fractionation and subsequent spectrophotometry indicated that betaine aldehyde dehydrogenase is predominantly in the cytosol with about 5% in the mitochondria. Of the aldehyde dehydrogenase activity (ALDH-I plus ALDH-II), 80% was found in the mitochondria and 20% in the microsomal fraction. Of the 2 enzymes, ALDH-I was exclusively mitochondrial and ALDH-II was distributed between mitochondria and microsomes. Submitochondrial fractionation indicated that betaine aldehyde dehydrogenase and ALDH-I are located in the matrix and ALDH-II is located chiefly in the outer membrane. These studies confirm the existence of 3 aldehyde dehydrogenases in the rat liver cell.

2629 EXPERIMENTAL STUDIES ON LIPID AND CARBOHYDRATE METABOLISM IN HUMAN LIVER BIOPSIES. *(Ger.)* Oette, K. (Med. Clin., Univ. Cologne, Germany). *Klin. Wochenschr.* 52(20):956-965, 1974.

Research on the effect of dietary fat and carbohydrate on lipid and carbohydrate metabolism in the human liver is reviewed. Studies were performed on human liver biopsies obtained with a Menghini needle and weighing 5-40 mg. When linolenic acid (40-100 g) was added to the diet as a metabolic indicator for long-chain fatty acids, no more than 12% was recovered from the liver, the amount depending upon the linolenic acid content of the diet. In two patients with minor atypical parenchymal changes but no steatosis, more linolenic acid was present in the phosphatide than in the glyceride fraction 5-6 hr after administration. Addition of 1-^{14}C-linolenic acid to the diet had no effect on the enzymes involved in fatty acid uptake and esterification in the liver, and the ratio of dietary carbohydrate to fat had no effect on total uptake nor on incorporation of fatty acids into the various lipid fractions. Diets with lower fat or higher carbohydrate contents reduced incorporation of 1-^{14}C-acetate into total lipids in the human liver. This anomalous finding is attributed either to intracellular dilution of 1-^{14}C-acetate by increased synthesis of inactive acetyl-coenzyme A from glucose or to a deficiency of coenzyme A (competitive inhibition). When a high-fat diet was administered, 1-^{14}C-acetate was used almost exclusively for chain lengthening, and the C_{20}-C_{22} polyunsaturated fatty acids formed were preferentially incorporated into the phosphatide fraction. Studies on the metabolism of U-^{14}C-hexoses and U-^{14}C-glycerol in the human liver revealed that, under the experimental and dietary conditions employed, glucose, fructose, and galactose were incorporated into the glycogen and glyceride fractions in the liver and only small amounts were used for *de novo* fatty acid synthesis. When the diet contained about 30-45% fat, calculated on a caloric basis, the rate of *de novo* phosphatide synthesis in the human liver was more than twice the rate of fatty acid synthesis when fructose was used as the carbohydrate. Fructose and galactose were used for glycogen synthesis to about the same extent, while glucose was used in far larger quantities. In the *in vitro* system employed, degradation products of fatty acids, particularly stearic acid, and fructose, rather than glucose, were the preferred precursors of cholesterol. A high-fat diet did not increase the rate of cholesterol synthesis. However, administration of ethanol for several days increased the rate of cholesterol, but not that of cholesterol ester, synthesis. If the results of these experiments can be extrapolated to *in vivo* conditions and plasma lecithin-cholesterol acyltransferase activities are taken into account, these findings confirm that the human liver is of minor importance for the synthesis of cholesterol esters.

2630 SYNTHESIS OF THE SULFATE ESTERS OF BILE ACIDS IN THE PERFUSED RAT LIVER AFTER BILE DUCT OCCLUSION. *(Ger.)* Liersch, M.; Stiehl, A. (Med. Clin., Univ. Heidelberg, Germany). *Z. Gastroenterol.* 12(2):131-134, 1974.

Synthesis of the sulfate esters of bile acids was studied in isolated perfused livers from male Sprague-Dawley rats. Cholestasis was induced 1-3 weeks before perfusion or immediately before perfusion with a hemoglobin-free medium (100 ml Krebs-Henseleit solution, 2.5 g bovine serum albumin, and 5.5 mM glucose) to which lithocholic acid (0.12 mM) or other ^{14}C-labeled bile acids (0.25×10^{-3} M) had been added. While livers from intact rats rapidly extracted bile acids from the perfusion medium, cholestatic livers removed only about 6 µM in 150 min of perfusion. After 150 min of perfusion, about 35% of lithocholic acid, but only 1-2% of cholic and chenodeoxycholic acids, had been converted to their sulfate esters. The duration of cholestasis had no effect on synthesis of the sulfate ester of lithocholic acid, but synthesis of the sulfate ester of taurocholic acid increased with the duration of cholestasis. Sulfate esters of taurocholic acid accounted for 2.6% of this when the bile ducts were occluded immediately before perfusion, but for 6% and 8% after 1 and 2 weeks of cholestasis, resp. Thin-layer chromatographic analysis of the medium after perfusion with free bile acids revealed that more than 95% of the bile acids were present in conjugated form after 150 min. Studies with cell-free extracts are being performed to determine whether free bile acids have to undergo conjugation with taurine before they can be converted to their sulfate esters.

2631 EXPERIMENTAL ALCOHOL-INDUCED HEPATIC NECROSIS: SUPPRESSION BY PROPYLTHIOURACIL. *(E.)* Israel, Y.; Kalant, H.; Orrego, H.; Khanna, J. M.: Videla, L.; Phillips, J. M. (Dep. Pharmacol., Univ.. Toronto, Canada). *Proc. Natl. Acad. Sci. USA* 72(3): 1137-1141, 1975.

The hypothesis that the hypermetabolic state that exists in the livers of animals treated chronically with ethanol produces a relative hypoxia in the centrilobular zone of the liver which, if severe enough, leads to cellular death and the production of hepatitis was tested in male Wistar rats. Rats consuming ethanol (35% of the total calories) for 30 days, given with a nutritionally adequate diet, and exposed to reduced oxygen tensions (11, 7.5, or 5%, the remainder being pure nitrogen) for 6 hr, developed histological and biochemical evidence of hepatocellular necrosis and inflammatory lesions confined to the centrilobular zone. The severity was proportional to the degree of hypoxia. Pair-fed (nonalcohol) controls showed no such lesions. Treatment of the animals with 6-propyl-2-thiouracil (5 mg/100 g daily) abolished the hypermetabolic state of the liver in ethanol-consuming animals, and reduced the histological and biochemical effects of hypoxia. Since 6-propyl-2-thiouracil reduced both the hypermetabolic state of the liver and susceptibility of the liver to damage by hypoxia in animals treated chronically with ethanol, it is concluded that the hypermetabolic state may be responsible for the supersensitivity to hypoxia. If a hypermetabolic state also occurs in the liver of the alcoholic patient, it is conceivable that a reduction in the availability of oxygen to the liver could explain the production of alcoholic hepatitis and that 6-propyl-2-thiouracil could also be therapeutically effective in the treatment of alcholic hepatitis in man.

2632 THE DISTRIBUTION OF BILE ACIDS IN HEPATOCYTES IN EXTRAHEPATIC CHOLESTASIS. II. *(Ger.)* Leuschner, U.; Kurtz, W.; Alfurayh, A.; Erb, W.; (Cent. Intern. Med., Johann Wolfgang Goethe Univ., Frankfurt/Main, Germany). *Z. Gastroenterol.* 12(3):163-168, 1974.

Extrahepatic cholestasis was induced in 17 male Wistar rats by double ligation of the bile duct, severing it just before the opening into the small intestine. After 17 days the rats were sacrificed and their livers were removed along with the dilated extrahepatic bile ducts. The larger intrahepatic bile ducts were emptied by gentle compression, bile was cleaned off from the surface of the liver, and the hepatic vein was perfused several times with a solution containing 0.3 M KCl and 0.05 of potassium EDTA. Liver homogenate was then fractioned in the above solution by differential centrifugation, and the fractions were analyzed for bile acids by gas chromatography. The mean bile acid content of a liver weighing 13.5 g was 157.6 µg. Of this bile acid, 8.3% was found in the mitochondria, 23.4% in the microsomes, and 68.3% in the supernatent or cytoplasmic fraction. In all three fractions the bile acid present in the highest concentration was cholic acid. While the highest concentrations of cholic acid were found in the microsomes and supernatant, the highest concentrations of β-muricholic and lithocholic acids were detected in the mitochondria and microsomes. Chenodeoxycholic acid was distributed uniformly throughout all fractions. In all fractions, total dihydroxy (deoxycholic and chenodeoxycholic) acids were present in concentrations less than 1/10 of the concentrations of trihydroxy (cholic and β-muricholic) acids. A comparison of these findings with the distribution of bile acids in the liver of normal rats showed that the total bile acid content was 69% lower in extrahepatic cholestasis. Bile acids were 34% lower in the mitochondria, 88.4% lower in the microsomes, but 102% higher in the supernatant. It is suggested that an increase in the concentration of trihydroxy bile acids results in impairment of synthesis in the hepatocytes in extrahepatic cholestasis.

2633 INFLUENCING THE MICROSOMAL ENZYME ACTIVITY IN THE RAT LIVER BY ETHANOL WITH AND WITHOUT DRUGS.

(Ger.) Bode, C.; Bode, J. C.; Martini, G. A. (Med. Clin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:909-910, 1973.

Groups of 8-10 male Wistar rats were given a standard diet containing 20% protein *ad libitum* and: 1) water; 2) 15% (w/v) ethanol solution *ad libitum*; 3) 15% ethanol solution *ad libitum* and 5 g/kg/day ethanol p.o. through a tube; 4) water and 100 mg/kg/day phenobarbital; and 5) water, 100 mg/kg/day phenobarbital, 15% ethanol *ad libitum*, and 5 g/kg/day ethanol p.o. through a tube. Two other groups of rats received a low protein diet (5% protein) with: 6) water; or 7) 15% ethanol solution *ad libitum* and 5 g/kg/day ethanol p.o. The activities of acetanilide hydroxylase (AAH) and NADPH- and NADH-dependent cytochrome c reductase (CcR) were reduced to about 50% of control values in groups 2 and 3, while activities of steroid reductase (SR) and glucose-6-phosphatase (G-6-P) were reduced by 150-200%. No significant differences in enzyme activities were found between group 2 and 3. In group 4, phenobarbital had no effect on the activities of AAH or NADH-dependent CcR, but it did increase the activities of NADPH-dependent CcR, SR, and G-6-P. In group 5, administration of both alcohol and phenobarbital increased only the activity of G-6-P; no changes occurred in the activities of the other enzymes studied. In group 6 a low-protein diet reduced the activities of AAH and NADH- and NADPH-dependent CcR to about 20-30% of control values. Combination of a low-protein diet with ethanol (group 7) had no further effect on microsomal enzyme activity. G-6-P activity was twice that of control values in groups 6 and 7, while SR activity was significantly reduced in groups 6 and 7. These findings demonstrate that ethanol has different effects on microsomal enzyme activity. The fact that chronic alcoholics sometimes eat protein-deficient diets and ingest sedatives or other drugs may account for reported discrepancies in drug metabolism in alcoholism.

2634 HORMONAL INFLUENCES IN THE DEVELOPMENT OF THE HYPERMETABOLIC STATE OF THE LIVER PRODUCED BY CHRONIC ADMINISTRATION OF ETHANOL.

(E.) Bernstein, J.; Videla, L.; Israel, Y. (Dep. Pharmacol., Univ. Toronto, Canada). *J. Pharmacol. Exp. Ther.* 192(3):583-591, 1975.

The relative participation of adrenaline and of thyroid hormones in the production of a liver hypermetabolic state induced by chronic ethanol administration was investigated in male Wistar rats. The animals were given ethanol by gastric intubation for 15-19 days in increasing doses: 3 g/kg for 3 days (as 20 w/v solution); 4 g/kg for 3 days (25% solution); 5 g/kg for 3 days (30% solution); and 6 g/kg (35% solution) for the remaining period. Thyroidectomized, adrenalectomized, and control animals in the ethanol-treated groups weighed 10-20 g less than dextrose-treated groups at the end of the treatment. In another experiment, animals were given liquid diets in which ethanol provided 35% of the total calories. Chronic administration of ethanol to the rats led to the development of a hypermetabolic state of the liver. The calorigenic effects produced by ethanol, measured in liver slices, could by reproduced by a single large dose of epinephrine (2 mg/kg s.c.). Oxygen consumption by liver slices of animals given this large dose of epinephrine bitartrate increased 40-50%. In these livers all the extra oxygen consumption, but not the basal respiration, could be abolished by ouabain, an inhibitor of the sodium pump. 2,4-Dinitrophenol did not affect the respiratory rate in the liver of epinephrine-treated animals but markedly increased that in controls. In the livers of treated animals, the activating effect of 2,4-dinitrophenol was recovered in the presence of ouabain. The calorigenic effect of epinephrine in the liver was completely abolished by phentolamine (α-adrenergic blocker) but was not modified by DL-propranolol (β-adrenergic blocker). The calorigenic effects produced by epinephrine were not seen in thyroidectomized animals or by incubating the liver slices in a calcium-free medium. It is concluded that thyroidectomy and administration of phentolamine markedly reduced, and adrenalectomy completely abolished, the hypermetabolic state produced in the liver of rats by chronic administration of ethanol.

2635 STEROID PROTECTION OF THE LIVER DURING EXPERIMENTAL ISCHEMIA.

(E.) Figueroa, I.; Santiago-Delpin, E. A. (Univ. Puerto Rico Med. Sch., San Juan). *Surg. Gynecol. Obstet.* 140(3):368-370, 1975.

The effect of steroids during transitory experimental warm hepatic ischemia was investigated in rabbits in which total hepatic ischemia was produced by ligating the portal triad and gastrohepatic ligament for 30 min. A survival rate of 10% was obtained in controls. If methylprednisolone was given (30 mg/kg i.v.) 5-10 min prior to occlusion, 100% of the rabbits survived. If methylprednisolone was given (30 mg/kg i.v.) immediately after occlusion, the survival rate was 54%. Further experiments extending occlusion to 1 hr resulted in a 50% survival rate with prior methylprednisolone administration as compared with no survivors among controls. Two hypotheses on the mechanism of methylprednisolone protection of the liver during ischemia are presented: 1) methylprednisolone prolongs the tolerance to actual ischemia by protecting the cell membrane or by stabilizing the lysozomal membrane of the ischemic hepatic cell; or 2) it inhibits or blocks the effect on the cardiovascular system of already circulating toxic substances liberated from the liver during the ischemic period. The fact that treatment before occlusion resulted in a more prolonged survival time than treatment after occlusion suggests that the first hypothesis is probably the most important one, even though the second must be operational as well.

2636 EFFECTS OF CHRONIC ETHANOL TREATMENT AND THYROXINE ADMINISTRATION ON ETHANOL METABOLISM AND LIVER OXIDATIVE CAPACITY. *(E.)* Israel, Y.; Videla, L.; Fernandex-Videla, V.; Bernstein, J. (Dep. Pharmacol., Univ. Toronto, Canada). *J. Pharmacol. Exp. Ther.* 192(3):565-574, 1975.

The rate of ethanol metabolism *in vivo* and by liver slices *in vitro* in male Wistar rats treated with thyroxine, was investigated in an effort to determine the cause for previously published contradictory reports on the effect of thyroid hormones on the rate of ethanol metabolism. The rats were given nutritionally complete liquid diets providing 35% of the total calories as ethanol for 21-27 days. The average daily alcohol intake of animals was 14.3 g/kg/day. This chronic administration of ethanol led to an increased rate of ethanol metabolism *in vivo* and *in vitro*. *In vitro* studies in liver slices showed that ouabain, an inhibitor of the $Na^+ + K^+$-activated ATPase, completely blocked the extra ethanol metabolism elicited by chronic ethanol treatment. 2,4-Dinitrophenol increased the rate of ethanol metabolism in the livers of the treated animals only in the presence of ouabain. Administration of thyroxine led to an increase in the rate of ethanol metabolism when measured both *in vitro* and *in vivo*. This effect was biphasic; an activation occurred only with low doses of thyroxine but disappeared after administration of larger doses. Alcohol dehydrogenase activity in the liver of the animals treated with large doses of thyroxine was reduced significantly. With the doses used (50-1000 g/kg), thyroxine also increased the rate of oxygen consumption as measured in liver slices. However, a biphasic effect did not occur. A near maximum activation on the rate of oxygen consumption occurred with low doses of thyroxine (100 μg/kg). Oxygen consumption was also increased in the livers of animals chronically treated with ethanol. A maximal effect was produced after 18-21 days of treatment. For both ethanol and thyroxine-treated animals, an increased rate of oxygen consumption occurred with a concomitant loss of dinitrophenol effect. Mitochondrial-glycerophosphate oxidase was increased in the liver of animals treated with ethanol or with thyroxine. In these two groups, this enzymatic activity appeared to be less affected by the treatment than the 2,4-dinitrophenol-activated respiration. Although these results show that chronic treatment with ethanol produces many changes in the liver that are similar to those produced by thyroid hormones, it is concluded that it is not possible to ascertain that the chronic effects of ethanol were only mediated by thyroid hormones.

2637 UDP-GLUCURONYLTRANSFERASE IN PERFUSED RAT LIVER AND IN MICROSOMES: INFLUENCE OF PHENOBARBITAL AND 3-METHYLCHOLANTHRHENE. *(E.)* Bock, K. W.; White, N. H. (Toxicol. Inst., Tubingen, Germany). *Eur. J. Biochem.* 46(3):451-459, 1974.

1-Naphthol glucoronide formation and liver uridine diphosphate (UDP)-glucuronate levels were determined in perfused livers from control, phenobarbital treated and 3-methyl cholanthrene-treated rats, and the rates of glucuronidation compared with UDP-glucuronyltransferase activity in native and microsomal preparations activated by Triton X-100 *in vitro*. Male Sprague-Dawley rats received 3 daily i.p. injections of 100 mg/kg/ phenobarbital and were sacrificed on the fourth day. Those rats treated with 3-methylcholanthrene were injected once i.p. with 40 mg/kg in olive oil; hepatectomy was performed on the fourth day. Galactosamine-HCl (400 mg/kg) was injected once i.p. 3 hr before sacrifice. Liver microsomal UDP-glucuronyltransferase (1-naphthol as substrate) was activated about 10-fold by treatment of native microsomes *in vitro* with Triton X-100. Following pretreatment with 3-methylcholanthrene or phenobarbital the specific activities of detergent-activated microsomes were increased about 300% and 40%, resp. In isolated liver perfused with 0.5 mM 1-naphthol, the rate of glucuronidation of naphthol as determined by the appearance of naphthol glucuronide in the perfusate, bile and liver tissue, was 0.1 μM/min/g liver. This rate of glucuronidation was increased by 70% in rats pretreated with 3-methylcholanthrene and 140% following phenobarbital treatment. A UDP-glucuronic acid level of 0.3 μm/g liver was determined in perfused liver from control rats. This level remained unchanged during perfusion with 0.5 mM 1-naphthol. In the perfused liver from phenobarbital or 3-methylcholanthrene treated rats, the UDP-glucuronate level increased to 0.5 μM/g liver. In control, 3-methylcholanthrene or phenobarbital-treated rats, rates of glucuronidation of 1-naphthol in the perfused liver system correspond best with the UDP-glucuronyltransferase activities determined in native microsomes when the different UDP-glucuronate levels, microsomal protein contents and liver weights are taken into account. The results suggest that the enzyme is mostly latent in the microsomal membrane and that this latency is increased after pretreatment of rats with 3-methylcholanthrene despite the marked enzyme induction.

2638 THE CHOLERETIC MECHANISMS OF SODIUM TAUROCHOLATE, SECRETIN, AND GLUCAGON. *(E.)* Russell, T. R.; Searle, G. L.; Jones, R. S. (VA Hosp., San Francisco, Calif.). *Surgery* 77(4):498-504, 1975.

The choleresis stimulated by sodium taurocholate, secretin, and glucagon was compared as was the effect of each of these substances on canalicular secretion as estimated by the biliary clearance of erythritol. Three mongrel dogs were prepared by cholecystectomy, ligation of the lesser pancreatic duct, and insertion of modified Thomas cannulas into the duodenum and stomach. After recovery from surgery, experiments were performed (as often as 3 times weekly but never on successive days) by cannulation of the common bile duct for bile collection through the duodenal cannula. After cannulation, bile and gastric juice were collected continuously at 15 min intervals for the duration of the experiment. Sodium chloride solution (0.9%) was infused i.v. throughout all experiments. Choleretic test substances were added at the end of the eighth 15-min period and the dose of each substance increased hourly for the remainder of the experiment. At the end of the fourth 15-min period, 3 μCi ^{14}C-labeled erythritol was injected i.v. and an i.v. infusion of [^{14}C]erythritol begun and continued at a rate of 3 μCi/hr for the remainder of the experiment. All test substances caused increased bile secretion. Sodium taurocholate caused a marked increase in bile salt output and in the biliary clearance of erythritol. Secretin caused a large increase in bile flow, no increase in bile salt output, and a very small increase in the biliary clearance of erythritol. The results indicate marked differences in the choleretic mechanism of sodium taurocholate and secretin and suggest that the principal action of taurocholate is on the canaliculi and the principal action of secretin is on the ducts.

2639 TIME COURSE OF PROTECTION BY N,N'-DIPHENYL-p-PHENYLENDIAMINE (DPPD) AGAINST CARBON TETRACHLORIDE HEPATOTOXICITY.

(E.) Torrielli, M. V.; Ugazio, G.; Gabriel, L.; Burdino, E. (Inst. Gen. Pathol., Univ. Turin, Italy). *Agents Actions* 4(5):383-390, 1974.

The mechanism of protection by *N*,*N*'-diphenyl-*p*-phenylenediamine (DPPD) against carbon tetrachloride intoxication was investigated in male Wistar rats. DPPD was suspended in 2.5% acacia gum and given i.p. 60 mg/100 g 48 and 24 hr before intoxication. CCl_4, either 25 or 250 μl/100g, was given p.o. in mineral oil. The preliminary treatment with DPPD prevented liver fatty infiltration after CCl_4 poisoning. Double bond shifting in microsomal lipids was depressed 30 min after intoxication. A more active protection took place with low doses of CCl_4 than after a large dose. In later stages of CCl_4 challenge, both triglyceride accumulation and lipid peroxidation took place in spite of DPPD treatment. However, they were less severe and more transient than in unprotected animals. Liver necrosis, as evidenced by changes in serum activity of alanine aminotransferase, was prevented by DPPD. When animals treated with either DPPD or its suspending medium were given ^{14}C-labeled CCl_4, and the exhaled $^{14}CO_2$ assayed by liquid scintillation spectrometry and the lipid-bound radiocarbon was assayed, it was found that DPPD did not interfere with the hepatic metabolism of CCl_4. Pretreatment with DPPD partially inhibited the *in vitro* demethylation of aminopyrine by liver microsomes and significantly potentiated the hypnotic effect of hexobarbital (12 mg i.p.). When injected along with phenobarbital (8 mg/100 g/day i.p. for 3 days), DPPD blocked the barbiturate stimulation of microsomal enzymes. A combined dosing with DPPD and CCl_4 caused a more severe inhibition of demethylase activity and hexobarbital metabolism. It is concluded that *N*,*N*'-diphenyl-*p*-phenylenediamine interferes with the metabolism of CCl_4 only up to the threshold level covering the development of the most common secondary phenomena induced by this haloalkane, but that the non-inhibited cleavage of carbon tetrachloride allows the primary attack to take place and to progress up to a certain extent.

2640 ETHANOL METABOLISM AND LIVER OXIDATIVE CAPACITY IN COLD ACCLIMATION.

(E.) Videla, L.; Flattery, K. V.; Sellers, E. A.; Israel, Y. (Dep. Pharmacol., Univ. Toronto, Canada). *J. Pharmacol. Exp. Ther.* 192(3):575-582, 1975.

The role of the $Na^+ + K^+$-activated ATPase system in changes leading to an increased oxidative capacity and an increased ethanol metabolism in the livers of male Wistar rats exposed to 5 C for 4 - 6 weeks was investigated. The animals were supplied with food and water *ad libitum*. The cold exposure led to 30-80% increases in the rate of oxygen consumption and a 50% increase in the rate of ethanol oxidation by liver slices, a 50% increase in mitochondrial α-glycerophosphate oxidase activity of liver, and a 100% increase in $Na^+ + K^+$ -activated ATPase activity. Ouabain (1mM), an inhibitor of the $Na^+ + K^+$ -activated ATPase, completely blocked the extra respiration and ethanol oxidation. 2,4-Dinitrophenol, which increases oxygen consumption and ethanol oxidation by liver slices from normal rats, was ineffective with slices from cold-exposed animals. The ethanol disappearance rate *in vivo* was also increased by cold acclimation, even though liver alcohol dehydrogenase activity was reduced. It is suggested that increased hydrolysis of ATP by the sodium pump system is responsiblle for the increased oxygen consumption and ethanol metabolism in the livers of cold-acclimated animals.

2641 SEQUENTIAL PRODUCTION OF FATTY LIVER, HEPATITIS, AND CIRRHOSIS IN SUB-HUMAN PRIMATES FED ETHANOL WITH ADEQUATE DIETS.

(E.) Lieber, C. S.; DeCarli, L. M.; Rubin, E. (VA Hosp., Bronx, N.Y.). *Proc. Natl. Acad. Sci. USA* 72(2):437-441, 1975.

An experimental model has been developed that reproduces the sequential development of all the liver lesions seen in the human alcoholic. Nine pairs of baboons were pair-fed an alcohol-containing or control liquid diet for 8-22 months, with the average length of treatment being 15 months. An additional group of 12 animals that had been given a solid diet with either alcohol or carbohydrates in the drinking water for a period varying from 17-34 months were changed to the liquid diet for an average of 17 months. The protein content of the diet (18% of total calories) corresponded to that of commonly used commercial diets that are satisfactory for the baboon. The incorporation of the ethanol (50% of total calories) in a totally liquid diet permitted the maintenance of a nutritionally adequate regimen despite the intake of inebriating amounts of ethanol. In the 15 baboons fed ethanol, all developed fatty liver, five progressed to hepatitis, and five had cirrhosis. Upon ethanol withdrawal, signs of physical dependence, such as seizures and tremors, developed. Surgical biopsies of the liver were performed at regular intervals under anesthesia. Ultrastructural changes of the mitochondria and the endoplasmic reticulum were already present at the fatty liver stage and persisted throughout hepatitis and cirrhosis. The lesions were similar to those observed in alcoholics (including the inflammation and the central sclerosis) and differed from the alterations produced by choline and protein deficiencies. At the fatty liver stage, some adaptive increases in activity of microsomal enzymes (aniline hydroxylase and the microsomal ethanol oxidizing system) were observed, but these tended to disappear with the development of hepatitis and cirrhosis. Fat accumulation was also much more pronounced in the animals with hepatitis as compared with those with simple fatty liver (an 18-fold compared with 3- to 4-fold increase in liver triglycerides). The demonstration that these lesions can develop despite an adequate diet indicates that in addition to correction of the nutritional status, control of alcohol intake is mandatory for the management of patients with alcoholic liver injury.

2642 THE INTERACTION OF VASOACTIVE INTESTINAL POLYPEPTIDE AND SECRETIN WITH LIVER-CELL MEMBRANES. *(E.)* Desbuquois, B. (INSERM, Hosp. Sick Child., Paris, France). *Eur. J. Biochem.* 46(3):439-450, 1974.

The interaction of vasoactive intestinal polypeptide (VIP) and secretin with isolated rat liver-cell membranes was investigated using ^{125}I-labeled derivatives of the hormones. Incorporation of iodine did not appreciably affect the ability of VIP to stimulate the activity of adenylate cyclase in liver membranes, but caused a 2-3 fold decrease in the apparent affinity of secretin towards this enzyme. Native VIP and secretin readily displaced [^{125}I]VIP specifically bound to liver cell membranes; about 100 times greater concentrations of secretin were necessary to achieve effects similar to those observed with VIP. Synthetic secretin displaced the VIP-membrane complex identically to natural secretin. The labeled material dissociated from the VIP-membrane complex retained the ability of unused VIP to bind to membranes but VIP in the incubation medium was rapidly inactivated upon exposure to membranes and to certain polypeptides, such as bacitracin. At 23 C, the rate of VIP-membrane association was 1.3 x 10^{7}/M/sec and the rate of dissociation, 2.3 x 10^{-3}/sec. The dissociation constant based on these rate constants is 0.17 nM; the value of 0.16 nM was obtained separately from equilibrium data. Binding of VIP to membranes was reduced by increasing the ionic strength of the medium. Maximum binding occurred at pH 7.4. Nucleoside di- and triphosphates decreased the binding of VIP to membranes at equilibrium and increased the rate of dissociation of the VIP-membrane complex. Digestion of the membranes with trypsin and phospholipase A resulted in a loss of the ability of these membranes to bind VIP. [^{125}I]secretin bound specifically to liver membranes. Binding was competitively inhibited by native secretin and VIP in a closely similar fashion to that of [^{125}I]VIP. Only a small fraction (2-3%) of the medium secretin bound to membranes. At equivalent concentrations, the iodinated derivative of natural secretin bound to membranes more effectively than that of the synthetic peptide. After incubation of natural [^{125}I]-secretin with liver membranes, the radioactive material eluted from the membranes with urea was about 3 times more potent than unused secretin in its ability to bind to fresh membranes. These findings suggest that a fraction of the iodinated derivative of natural secretin which binds to membranes is probably iodinated VIP present as a contaminant. It is further suggested that the vasoactive intestinal polypeptide binding structures identified in liver cell membranes represent biological receptors for this hormone.

2643 MULTICOMPARTMENTAL ANALYSES OF TWO- AND THREE-EXPONENTIAL PLASMA DISAPPEARANCE CURVES AFTER INTRAVENOUS INJECTION OF ^{14}C-CHOLIC ACID, SULFOBROMOPHTHALEIN, AND ^{14}C-BILIRUBIN: THEIR VALUE IN QUANTITATIVE STUDIES OF HEPATIC EXCRETION. *(Ger.)* Klapdor, R.; Eppers, J. (1st Med. Clin., Univ. Hamburg, Germany). *Z. Gastroenterol.* 12(1): 1-8, 1974.

In a study of eight miniature pigs, anesthetized with pentobarbital sodium, it was demonstrated that the distribution and excretion of ^{14}C-cholic acid, BSP, and ^{14}C-bilirubin after a single i.v. injection can be calculated from 3-exponent plasma clearance curves by a 3-compartment metabolic model. This model was derived from a 2-compartment model used to analyze 2-exponent plasma clearance curves after i.v. injection of these substances. Since plasma clearances after a single i.v. injection of ^{14}C-cholic acid, BSP, and ^{14}C-bilirubin can be described, in most cases, as 2- or 3-exponent, these substances can be employed as bile markers. By comparing calculated values for these substances and their concentrations measured in the bile or duodenal juice, it is possible to detect impairment of bile flow or a loss of hepatic bile on its course from the liver to a tube, no matter whether this loss results from discharge into the gallbladder or incomplete aspiration of duodenal juice.

2662 HEPATOCELLULAR HYALIN (MALLORY BODIES) IN LONG TERM GRISEOFULVIN TREATED MICE. *(E.)* Denk, H.; Gschnait, F.; Wolff, K. (Dep. Pharmacol., Univ. Vienna, Austria). *Fed. Proc.* 34(3):843, 1975.

2663 EFFECT OF KETO ACIDS ON METHIONINE METABOLISM BY RAT LIVER HOMOGENATES. *(E.)* Mitchell, A. D.; Benevenga, N. J. (Univ. Wisconsin, Madison). *Fed. Proc.* 34(3):885, 1975.

2664 PHARMACOKINETICS OF AZATHIOPRIN IN ANIMAL EXPERIMENTS AND PATIENTS WITH CHRONIC LIVER DISEASES. *(Ger.)* Bar, U.; Becker, H.; May, B.; Mayer, D.; Ohlendorf, S.; Otto, P.; Schmidt, F. W. (Med. Coll., Hanover, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:943-946, 1973.

2665 EFFECT OF NONTOXIC DOSES OF F AND S SALTS ON RAT LIVER METABOLISM IN VIVO. *(E.)* Allmann, D. W.; Mapes, J. P.; Benac, M. (Indiana Univ. Sch. Med., Indianapolis). *J. Dent. Res.* 54 (1):189, 1975.

2666 INFLUENCE OF CYCLOLEUCINE ON METABOLISM AND ACUTE EFFECT OF ETHIONINE. *(E.)* Brada, Z.; Novak, M.; Bulba, S.; Penn-Walker, D. (Papanicolaou Cancer Res. Inst., Univ. Miami, Fla.). *Fed. Proc.* 34(3):843, 1975.

2667 THE INFLUENCE OF DIHYDROERGOTAMINE ON THE RESULTS OF INTRAVENOUS PERFUSIONS OF GALACTOSE. *(Fr.)* Charbonnier, A.; Nepveux, P.; Fluteau, G.; Fluteau, D. (Cochin Hosp. Cent., Paris, France). *Ann. Gastroenterol. Hepatol. (Paris)* 10(3): 197-208, 1974.

2668 PERFUSION OF THE HUMAN LIVER IN THE PRESENCE OF PHARMACOLOGICAL DOSES OF GLUCAGON. *(Ger.)* Wicklmayr, M.; Dietze, G.; Czempiel, H.; Hepp, K. D.; Mehnert, H.; Henftling, H. G. (Schwabinger Hosp., Munich, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79: 933-936, 1973.

2669 AFFINITY OF UDP GLUCORONYL TRANSFERASE FOR CHLORAMPHENICOL. *(Ger.)* Linhart, P. (Med. Clin., Univ. Heidelberg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:936-938, 1973.

2670 NECROSIS PRODUCED BY HEPATIC ARTERIAL LIGATION IN ALCOHOL-FED RATS. *(E.)* Kalant, H.; Israel, Y.; Phillips, M. J.; Woo, N.; Khanna, J. M.; Orrego, H. (Univ. Toronto, Canada). *Fed. Proc.* 34(3):719, 1975.

2671 LIVER HYPERMETABOLIC STATE AND EXPERIMENTAL NECROSIS AFTER CHRONIC ALCOHOL INGESTION: SUPRESSION BY PROPYLTHIOURACIL. *(E.)* Israel, Y.; Kalant, H.; Orrego, H.; Khanna, J. M.; Videla, L.; Phillips, M. J. (Dep. Pharmacol., Univ. Toronto, Canada). *Fed. Proc.* 34(3):719, 1975.

2672 HEPATIC MICROSOMAL ALCOHOL OXIDIZING SYSTEM (MAOS): ADAPTIVE INCREASE IN ACTIVITY FOLLOWING CHRONIC ETHANOL CONSUMPTION BY A CATALASE INDEPENDENT MECHANISM. *(E.)* Teschke, R.; Hasumura, Y.; Lieber, C. S. (VA Hosp., Bronx, N.Y.). *Fed. Proc.* 34(3):719, 1975.

2673 AGE-RELATED CHANGES IN ETHANOL METABOLISM. *(E.)* Rodgers, J.; Schulman, M. P. (Dep. Pharmacol., Univ. Illinois, Chicago). *Fed. Proc.* 34(3):719, 1975.

2674 EFFECT OF ETHANOL INGESTION AND SUBSEQUENT WITHDRAWAL ON HEPATIC METABOLITES IN YOUNG MINIATURE SWINE. *(E.)* Kusewitt, D. F.; Burke, J. P.; Tumbleson, M. E. (Dep. Vet. Med., Univ. Missouri, Columbia). *Fed. Proc.* 34(3):895, 1975.

2675 DECREASED ACETALDEHYDE (AC) OXIDATION BY LIVER MITOCHONDRIA AFTER CHRONIC ETHANOL CONSUMPTION. *(E.)* Hasumura, Y.; Teschke, R.; Lieber, C. S. (VA Hosp., Bronx, N.Y.). *Fed. Proc.* 34(3):895, 1975.

2676 ETHYL ALCOHOL AND LIVER TRYPTOPHAN OXYGENASE. *(E.)* Kumar, G. K.; Sardesai, V. M. (Wayne State Univ. Sch. Med., Detroit, Mich.). *Fed. Proc.* 34(3):895, 1975.

2677 CONTRIBUTION OF PLASMA FREE FATTY ACIDS TO HEPATIC TRIGLYCERIDE ACCUMULATION AFTER AN ACUTE DOSE OF ETHANOL. *(E.)* Abrams, M. A.; Cooper, C. (Case West. Res. Univ., Cleveland, Ohio). *Fed. Proc.* 34(3):844, 1975.

2678 RELATION BETWEEN THE PHOSPHOLIPID COMPOSITION OF PLASMA AND LIVER MICROSOMES IN EXPERIMENTAL CHOLESTASIS AND HEPATITIS IN ANIMALS. *(Ger.)* Gallenkamp, H.; Brachtel, D.; Richter, E. (Med. Clin., Univ. Wurzburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:930-933, 1973.

2679 LIPID PEROXIDATION AND GLUTATHIONE PEROXIDASE ACTIVITY IN THE LIVER OF CHOLESTEROL-FED RATS. *(E.)* Tasl, A. C.; Lin, R. (Sch. Public Health, Univ. Michigan, Ann Arbor). *Fed. Proc.* 34 (3):891, 1975.

2680 METABOLIC EFFECTS OF HYPOLIPEMIC DRUGS ON RAT LIVER MICROSOMAL ENZYMES AND CYTOPLASMIC PROTEINS. *(E.)* Machinist, J. M.; Ahn, K.; Becker, B. A. (Abbott Lab., North Chicago, Ill.). *Fed. Proc.* 34(3):725, 1975.

2681 INFLUENCE OF DIETARY FATTY ACIDS ON MEMBRANE PROPERTIES AND ENZYME ACTIVITIES OF LIVER MITOCHONDRIA OF NORMAL AND HYPOPHYSECTOMIZED RATS. *(E.)* Haeffner, E. W.; Privett, O. S. (Hormel Inst., Univ. Minnesota, Austin). *Lipids* 10(2): 75-81, 1975.

2682 STUDIES ON THE FORMATION OF LIPID PEROXIDES AND ON SOME ENZYMIC ACTIVITIES IN THE LIVER OF VITAMIN E-DEFICIENT RATS. *(E.)* Bonetti, E.; Abbondanza, A.; Della Corte, E.; Novello, F.; Stirpe, F. (Inst. Gen. Pathol., Univ. Bologna, Italy). *J. Nutr.* 105(3):364-371, 1975.

2683 AN EVALUATION OF SEVERAL HYPERLIPIDEMIC MODEL SYSTEMS: RELATIONSHIP BETWEEN SERUM LIPID LEVELS AND IN VIVO HEPATIC LIPID SYNTHESIS. *(E.)* Sullivan, A. C.; Triscari, J.; Miller, O. N. (Dep. Biochem. Nutr., Hoffmann-La Roche Inc., Nutley, N.J.). *Fed. Proc.* 34(3):788, 1975.

2684 OBLIGATORY ROLE OF LIPID PEROXIDATION IN CCl_4 INDUCED LOSS OF GLUCOSE-6-PHOSPHATASE AND CYTOCHROME P-450. *(E.)* Glende, Jr., E. A.; Hruszkewycz, A.; Recknagel, R. O. (Case West. Res. Univ., Cleveland, Ohio). *Fed. Proc.* 34(3):742, 1975.

2685 DEPRESSION OF HEPATIC TRIGLYCERIDE WITH RIBOFLAVIN IN THE RABBITS FED HIGH CHOLESTEROL DIET. *(E.)* Lin, J. K.; Chang, H. W.; Lee, J. D.; Tung, T. C. (Coll. Med., Natl. Taiwan Univ., Taipei). *J. Formosan Med. Assoc.* 73(7):353-358, 1974.

2686 INCREASED CHOLESTEROL-ESTER FORMATION DURING FORCED CHOLESTEROL SYNTHESIS IN RAT HEPATOCYTES. *(E.)* Nilsson, A. (Dep. Physiol. Chem., Univ. Lund, Sweden). *Eur. J. Biochem.* 51(2): 337-342, 1975.

2687 EFFECT OF CLOFIBRATE ON HEPATIC MICROSOMAL HYDROXYLATION OF CHOLESTEROL AND ETHYLMORPHINE IN RAT. *(E.)* Mellon, W. S.; Goldberg, A. P.; Witiak, D. T.; Feller, D. R. (Coll. Pharm., Ohio State Univ., Columbus). *Fed. Proc.* 34(3):725, 1975.

2688 STIMULATION BY OLEIC ACID OF HEPATIC BIOSYNTHESIS OF CHOLESTEROL AND CHOLESTERYL ESTERS. *(E.)* Goh, E. H.; Heimberg, M. (Dep. Pharmacol., Vanderbilt Univ., Nashville, Tenn.). *Fed. Proc.* 34(3):788, 1975.

2689 A RELIABLE, SENSITIVE, AND CONVENIENT RADIOACTIVE ASSAY FOR BENZPYRENE MONOOXYGENASE. *(E.)* DePierre, J. W.; Moron, M. S.; Johannesen, K. A. M.; Ernster, L. (Arrhenius Lab., Univ. Stockholm, Sweden). *Anal. Biochem.* 63(2): 470-484, 1975.

2690 LOW TEMPERATURE COLUMN CHROMATOGRAPHY: APPLICATION TO MICROSOMAL HYDROXYLATING SYSTEM. *(E.)* Balny, C.; Le Peuch, C.; Debey, P. (Inst. Biol. Phys. Chem., Paris, France). *Anal. Biochem.* 63(2):321-330, 1975.

2691 A PROTEIN FROM POLYMORPHONUCLEAR LEUKOCYTES (LEM) WHICH AFFECTS THE RATE OF HEPATIC AMINO ACID TRANSPORT AND SYNTHESIS OF ACUTE-PHASE GLOBULINS. *(E.)* Wannemacher, Jr., R. W.; Pekarek, R. S.; Thompson, W. L.; Curnow, R. T.; Beall, F. A.; Zenser, T. V.; DeRubertis, F. R.; Beisel, W. R. (US Army Med. Res. Inst. Infect. Dis., Fort Detrick, Frederick, Md.). *Endocrinology* 96(3):651-661, 1975.

2692 β-HYDROXY-3-METHYLGLUTARYL COENZYME A (HMG-CoA) REDUCTASE ACTIVITY IN HAMSTERS ON CHOW AND LITHOGENIC DIETS. *(E.)* Ginsberg, R.; Duane, W.; Flock, E. V. (Phoenix Clin. Res. Sect. Ariz.). *Fed. Proc.* 34(3):660, 1975.

2693 5'-NUCLEOTIDASE OF CHICKEN LIVER: A COMPARISON OF SOLUBLE 5'-NUCLEOTIDASE ACTIVITIES IN CHICKEN AND RAT LIVER. *(E.)* Naito, Y.; Itoh, R.; Tsushima, K. (Sch. Med., Yokohama City Univ., Japan). *Int. J. Biochem.* 5(11/12):807-810, 1974.

2694 EFFECT OF GALACTOSAMINE ON THE MICROSOMAL MIXED FUNCTION OXIDASES IN RAT LIVER. *(E.)* Ishii, H.; Morita, A.; Shigeta, Y.; Tsuchiya, M. (Keio Univ. Hosp., Tokyo, Japan). *Fed. Proc.* 34(3): 843, 1975.

2695 ENERGY-LINKED REACTIONS OF BIOTIN-DEFICIENT RAT LIVER MITOCHONDRIA. *(E.)* Bhuvaneswaran, C.; Dakshinamurti, K. (Dep. Biochem., Univ. Manitoba, Winnipeg, Canada). *Int. J. Biochem.* 5(11/12):819-822, 1974.

2696 UREA SYNTHESIS AND THE REDOX STATE OF NAD(P) IN ISOLATED RAT HEPATOCYTES. *(E.)* Gimpel, J. A.; DeLeeuw, G.; Vaartjes, W. J. (Johnson Res. Found., Univ. Pennsylvania, Philadelphia). *Fed. Proc.* 34(3):573, 1975.

2697 GLUCONEOGENESIS FROM L-CYSTEINE IN THE PERFUSED RAT LIVER. *(E.)* Simpson, R. C.; Hill, F. W.; Freedland, R. A. (Sch. Vet. Sci., Univ. California, Davis). *J. Nutr.* 105(3):379-384, 1975.

2698 FACTORS AFFECTING THE RATE OF GLUCONEOGENESIS FROM L-CYSTEINE IN THE PERFUSED RAT LIVER. *(E.)* Simpson, R. C.; Freedland, R. A. (Sch. Vet. Sci., Univ. California, Davis). *Fed. Proc.* 34 (3):885, 1975.

2699 ROLE OF CALCIUM IN GLUCONEOGENESIS AND GLYCOGENOLYSIS BY ISOLATED RAT LIVER CELLS. *(E.)* Pointer, R. H. (Div. Biol. Med. Sci., Brown Univ., Providence, R.I.). *Fed. Proc.* 34(3): 395, 1975.

2700 FUNCTIONAL CONTROL OF THE BILIARY TRACT. *(E.)* Stasiewicz, J.; Wormsley, K. G. (Med. Sch., Bialystok, Poland). *Acta Hepatogastroenterol. (Stuttg.)* 21(6):450-468, 1974.

2701 SEX DIFFERENCES IN CHOLIC ACID (CA) METABOLISM IN THE ISOLATED PERFUSED RAT LIVER (IPRL). *(E.)* Fisher, M. M.; Yousef, I. M. (Dep. Med. Pathol., Univ. Toronto, Canada). *Fed. Proc.* 34(3):844, 1975.

2702 THE RATE OF SYNTHESIS OF PROTEINS OF SUBFRACTIONS FROM A BILE CANALICULAR MEMBRANE RICH PREPARATION (BCM) IN THE RAT. *(E.)* Balabaud, C.; Gumucio, J. J.; Gray, R.; Kline, A. J. (Univ. Michigan, Ann Arbor). *Fed. Proc.* 34(3):395, 1975.

2703 INFLUENCE OF PHENOBARBITAL TREATMENT ON TOTAL AND INDIVIDUAL BILE ACID LEVELS IN THE SERUM AND LIVER OF INTACT RATS AND RATS WITH ALPHA-NAPHTHYLISOTHIOCYANATE-INDUCED CHOLESTASIS. *(Ger.)* Leinweber, W.; Muhlenkamp, H.; Erb, W. (Cent. Intern. Med., Frankfurt/Main, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:955-956, 1973.

2704 EFFECTS OF PHENOBARBITAL ON BILE ACID SYNTHESIS IN TWO STRAINS OF RATS. *(E.)* Mosbach, E. H.; Cohen, B. I.; Raicht, R. F.; Nicolau, G. (PHRI, New York, N.Y.). *Fed. Proc.* 34(3):891, 1975.

2705 A RETROGRADE PUSH BACK (RPB) TECHNIQUE FOR ESTIMATING DISTENDED BILIARY TREE CAPACITY IN RATS. *(E.)* Fujimoto, J. M. (Med. Coll. Wisconsin, Milwaukee). *Fed. Proc.* 34(3):711, 1975.

2706 EFFECT OF DIMETHYL SULFOXIDE ON THE HEPATIC DISPOSITION OF CHEMICAL CARCINOGENS. *(E.)* Levine, W. G. (Albert Einstein Coll. Med., Yeshiva Univ., Bronx, N.Y.). *Ann. NY Acad. Sci.* 243:185-193, 1975.

2707 POSTNATAL CHANGES IN THE LOCALIZATION OF GLUCOSE 6-PHOSPHATASE ACTIVITY WITHIN THE LIVER LOBULE OF THE MOUSE. *(E.)* Kanamura, S. (Chest Dis. Res. Inst., Kyoto Univ., Japan). *Anat. Rec.* 181(3):635-640, 1974.

2708 EXPERIMENTAL HEPATIC SUPPORT. *(It.)* Cavallari, A.; Bellusci, R.; Faenza, A.; Piccinni, L.; Mazziotti, A.; Ussia, G. (Inst. Surg. Clin. II, Univ. Bologna, Italy). *Minerva Chir.* 29(18):974-981, 1974.

2709 CHANGES IN THE PHARMACOKINETICS OF DRUGS IN DOGS WITH PORTACAVAL SHUNTS. *(Ger.)* Gugler, R. (Med. Clin., Univ. Bonn, Germany). *Z. Gastroenterol.* 12(Suppl.):408, 1974.

2710 STUDIES ON THE PATHOGENESIS OF EXPERIMENTAL ACTIVE CHRONIC HEPATITIS (ACH) IN THE RABBIT. *(Ger.)* Hopf, U.; Meyer zum Buschenfelde, K. H. (2nd Med. Clin., Univ. Mainz, Germany). *Z. Gastroenterol.* 12(Suppl.):410-411, 1974.

2711 EFFECT OF CARBON TETRACHLORIDE ON THE QUALITY OF HEPATIC COLLAGEN. *(Fr.)* Bazin, S.; Briquelet, N.; Allain, J. C.; Delaunay, A. (Pasteur Inst., Garches, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 280(4):517-520, 1975.

2712 ALLOSTERIC INHIBITION OF NUCLEAR ENDORIBONUCLEASE ACTIVITY BY A NATURAL INHIBITOR. *(Rus.)* Skridonenko, A. D. (Odessa Res. Inst. Balneol., USSR). *Dokl. Akad. Nauk SSSR* 221(1):232-234, 1975.

2713 EXTRACORPOREAL PERFUSION OF THE LIVER IN SWINE. *(It.)* Tygstrup, N. (Rikshosp. Copenhagen, Denmark). *Minerva Chir.* 29(18):994-1001, 1974.

2714 THE AGING OF HEPATIC LACTATE DEHYDROGENASE AND CELL RENEWAL IN THE RAT. *(Fr.)* Schapira, F.; Weber, A.; Gregori, C. (Cochin Univ. Hosp. Cent., Paris, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 280(9):1161-1163, 1975.

2715 HEPATIC MICROSOMAL DRUG-METABOLIZING ENZYMES IN RATS BEARING GUERIN CARCINOMA FOR VARIOUS PERIODS. *(E.)* Basu, T. K.; Parke, D. V.; Williams, D. C. (Dep. Biochem., Univ. Surrey, England). *Cytobios* 11(42):71-74, 1974.

2716 THE RESPONSE OF KEY GLUCONEOGENIC ENZYMES IN BOVINE LIVER TO VARIOUS DIETARY AND HORMONAL REGIMES. *(E.)* Baird, G. D.; Young, J. L. (Inst. Res. Anim. Dis., Agric. Res. Counc., Compton, England). *J. Agric. Sci.* 84(2):227-230, 1975.

2717 INTERACTIONS OF GLUCAGON, GUT GLUCAGON, VASOACTIVE INTESTINAL POLYPEPTIDE AND SECRETIN WITH LIVER AND FAT CELL PLASMA MEMBRANES: BINDING TO SPECIFIC SITES AND STIMULATION OF ADENYLATE CYCLASE. *(E.)* Bataille, D.; Freychet, P.; Rosselin, G. (INSERM, St. Antoine Hosp., Paris, France). *Endocrinology* 95(3):713-721, 1974.

2718 PORTACAVAL SHUNT IN THE NORMAL RAT. (i) THE ACUTE EFFECTS. *(E.)* Hickman, R.; Meyers, O. L.; Keraan, M.; Engelbrecht, G. H. C.; Webber, B.; Saunders, S. J.; Terblanche, J. (Dep. Med., Univ. Cape Town, South Africa). *S. Afr. J.* a). *Surg.* 12(2):78, 1974.

2719 TRANSHEPATIC METABOLISM FOLLOWING PORTACAVAL SHUNT IN THE YOUNG PIG. *(E.)* Hickman, R.; Saunders, S. J.; Terblanche, J. (Dep. Surg., Univ. Cape Town, South Africa). *S. Afr. J. Surg.* 12(2):64, 1974.

2720 EFFECT OF CHOLESTEROL FEEDING ON CHOLESTEROL BIOSYNTHESIS IN MATERIAL AND FOETAL RAT LIVER. *(E.)* Calandra, S.; Quartaroli, G. C.; Montaguti, M. (Inst. Gen. Pathol., Univ. Modena, Italy). *Eur. J. Clin. Invest.* 5(1):27-31, 1975.

2721 GLUCOCORTICOID INHIBITION OF PROTEIN SYNTHESIS IN VIVO AND IN VITRO. *(E.)* Kim, Y. S.; Kim, Y. (St. Louis Univ. Sch. Med., Mo.). *J. Biol. Chem.* 250(6):2293-2298, 1975.

2722 THE ROLE OF METAL IN LIVER ALCOHOL DEHYDROGENASE CATALYSIS. SPECTRAL AND KINETIC STUDIES WITH COBALT-SUBSTITUTED ENZYME. *(E.)* Shore, J. D.; Santiago, D. (Henry Ford Hosp., Detroit, Mich.). *J. Biol. Chem.* 250(6):2008-2012, 1975.

2723 DEOXYRIBONUCLEASES AND NUCLEIC ACID CONTENT OF RAT LIVER UNDER THE INFLUENCE OF SINGLE TOXIC DIETHYLNITROSAMINE DOSES. *(E.)* Hollatz, R.; Tempel, K.; Wulffius, M. (Inst. Pharmacol. Toxicol. Pharm., Fac. Anim. Husb., Univ. Munich, Germany). *Experientia* 31(1):87-88, 1975.

2724 PHENOBARBITAL AND THE PROTEIN SYNTHESIS OF LIVER RIBOSOMES. *(E.)* Tragl, K. H.; Chiari, R. (Med. Clin. I, Univ. Vienna, Austria). *Acta Hepatogastroenterol. (Stuttg.)* 21(6):433-437, 1974.

2725 LIVER AND PLASMA LIPIDS IN RATS FED CASEIN REACTED WITH OXIDIZED ETHYL LINOLEATE. *(E.)* Yanagita, T.; Sugano, M. (Dep. Food Sci. Tech., Kyushu Univ. Sch. Agric., Fukuoka, Japan). *Agric. Biol. Chem.* 39(1):63-69, 1975.

2726 THE EFFECT OF FOOD RESTRICTION ON BODY WEIGHT, NITROGEN BALANCE AND LIVER COMPOSITION OF ADULT RATS. *(E.)* Khan, M. A.; Bender, A. E. (Dep. Nutr., Agric. Univ., Lyallpur, Pakistan). *Pakistan J. Ind. Res.* 17(1):18-20, 1974.

2727 PROTECTION OF MICROSOMAL DRUG BIOTRANSFORMATION ENZYMES AGAINST CARBON TETRACHLORIDE BY DIETHYLDITHIOCARBAMATE IN RAT LIVER. *(E.)* Vainio, H.; Parkki, M. G. (Dep. Physiol., Univ. Turku, Finland). *Res. Commun. Chem. Pathol. Pharmacol.* 9(3):511-522, 1974.

2728 EFFECT OF GLUCAGON, EPINEPHRINE, CYCLIC 3',5'-AMP, N^6-2'-O-DIBUTYRYL CYCLIC 3',5'-AMP AND INSULIN UPON THE PHOSPHATE EXCHANGE OF THE ISOLATED PERFUSED FED RAT LIVER. *(E.)* De Venanzi, F.; Pena, F.; Jimenez, V. O.; De Alvarado, H. (Inst. Exp. Med., Cent. Univ. Venezuela, Caracas). *Endocrinology* 95(3):741-748, 1974.

2729 INTERACTION OF CHINOFORM WITH ELECTRON TRANSFER SYSTEM OF RAT LIVER MICROSOMES. *(E.)* Yagi, K.; Ohishi, N.; Takai, A.; Hattori, S. (Fac. Med., Univ. Nagoya, Japan). *Experientia* 30(12): 1430-1432, 1974.

2730 IRREVERSIBLE BINDING OF CARBON TETRACHLORIDE TO MICROSOMAL PHOSPHOLIPIDS. FREE RADICAL NATURE OF THE REACTIVE SPECIE AND ALTERATIONS IN THE PHYSICO-CHEMICAL PROPERTIES OF THE TARGET FATTY ACIDS. *(E.)* Villarruel, M. C.; Castro, J. A. (Lab. Chem. Bio-Toxicol., CITEFA, Zufriategui y Varela, Argentina). *Res. Commun. Chem. Pathol. Pharmacol.* 10(1):105-116, 1975.

2731 EXPERIMENTAL EXTRACORPOREAL LIVER PERFUSION IN VIVO WITH DAUNOMYCIN AND 5-FLUORO-URACIL. *(E.)* Tonnesen, K.; Fischerman, K.; Jorgensen, K.; Hansen, I.; Christoffersen, P. (Rigshosp., Copenhagen, Denmark). *Acta. Chir. Scand.* 140(8):631-634, 1974.

2732 CONTROL MECHANISMS OF LECITIN [SIC!] SYNTHESIS IN HUMAN LIVER. *(E.)* Schersten, T. (Sahlgrenska Hosp., Univ. Goteborg, Sweden). *Scand. J. Clin. Lab. Invest.* 34(Suppl. 141):71-72, 1974.

2733 MASCULINIZATION OF RAT LIVER ENZYME ACTIVITIES FOLLOWING HYPOPHYSECTOMY. *(E.)* Gustafsson, J. A.; Stenberg, A. (Dep. Germfree Res., Karolinska Inst., Stockholm, Sweden). *Endocrinology* 95(3):891-896, 1974.

2734 INCREASE IN HEPATIC CARNITINE ACETYLTRANSFERASE ACTIVITY ASSOCIATED WITH PEROXISOMAL (MICROBODY) PROLIFERATION INDUCED BY THE HYPOLIPIDEMIC DRUGS CLOFIBRATE, NAFENOPIN, AND METHYL CLOFENAPATE. *(E.)* Moody, D. E.; Reddy, J. K. (Univ. Kansas Med. Cent., Kansas City). *Res. Commun. Chem. Pathol. Pharmacol.* 9(3):501-510, 1974.

2735 LIVER GLUTATHIONE PEROXIDASE ACTIVITY AND CCl_4-INDUCED LIPID PEROXIDATION IN SELENIUM TREATED RATS. *(E.)* Bendetti, A.; Ferrali, M.; Casini, A.; Comporti, M. (Inst. Gen. Pathol., Univ. Siena, Italy). *Res. Commun. Chem. Pathol. Pharmacol.* 9(4):711-722, 1974.

2736 PRODUCTION OF A METHEMOGLOBIN-FORMING METABOLITE OF 3,4-DICHLOROANILINE BY LIVER IN VITRO. *(E.)* Chow, A. Y. K.; Murphy, S. D. (Sch. Public Health, Harvard Univ., Boston, Mass.). *Bull. Environ. Contam. Toxicol.* 13(1):9-13, 1975.

2737 INCREASE IN CYSTATHIONINE β-SYNTHASE ACTIVITY IN THE LIVER OF RATS TREATED WITH L-ETHIONINE. *(E.)* Koracevic, D. (Fac. Med., Nis, Yugoslavia). *Experientia* 31(1):26-27, 1975.

2738 INFLUENCE OF DIETARY FATTY ACIDS ON MEMBRANE PROPERTIES AND ENZYME ACTIVITIES OF LIVER MITOCHONDRIA OF NORMAL AND HYPOPHYSECTOMIZED RATS. *(E.)* Haeffner, E. W.; Privett, O. S. (Hormel Inst., Univ. Minnesota, Austin). *Lipids* 10(2):75-81, 1975.

2739 THE OCCURRENCE OF MULTIPLE FORMS OF CYTOCHROME P-450 IN HEPATIC MICROSOMES FROM UNTREATED RATS AND MICE. *(E.)* Mailman, R. B.; Tate, L. G.; Muse, K. E.; Coons, L. B.; Hodgson, E. (Dep. Entomol., North Carolina State Univ., Raleigh). *Chem. Biol. Interact.* 10(3):215-228, 1975.

2740 FACTORS DETERMINING SUCCESSFUL LIVER PRESERVATION FOR TRANSPLANTATION. *(E.)* Toledo-Pereyra, L. H.; Simmons, R. L.; Najarian, J. S. (Univ. Minnesota Hosp., Minneapolis). *Ann. Surg.* 181(3):289-298, 1975.

2741 GROWTH CONTROL OF DIFFERENTIATED FETAL RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE. V. OCCURRENCE IN DIALYZED FETAL BOVINE SERUM OF MACROMOLECULES HAVING BOTH POSITIVE AND NEGATIVE GROWTH REGULATORY FUNCTIONS. *(E.)* Leffert, H. L. (Cell Biol. Lab., Salk Inst., San Diego, Calif.). *J. Cell Biol.* 62(3):767-779, 1974.

2742 HORMONAL MECHANISMS REGULATING HEPATIC STEROID METABOLIZING ACTIVITIES. ESTROGENIC INDUCTION OF A CORTICOSTERONE-METABOLIZING ENZYME IN THE REGENERATING LIVER FROM CASTRATED MALE RATS. *(E.)* Eriksson, H. (Chem. Inst. 1, Karolinska Inst. Stockholm, Sweden). *Eur. J. Biochem.* 46(3):603-611, 1974.

2743 GROWTH CONTROL OF DIFFERENTIATED FETAL RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE. VII. HORMONAL CONTROL OF DNA SYNTHESIS AND ITS POSSIBLE SIGNIFICANCE TO THE PROBLEM OF LIVER REGENERATION. *(E.)* Leffert, H. L. (Cell Biol. Lab., Salk Inst., San Diego, Calif.). *J. Cell Biol.* 62(3): 792-801, 1974.

2744 GROWTH CONTROL OF DIFFERENTIATED FETAL RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE. VI. STUDIES WITH CONDITIONED MEDIUM AND ITS FUNCTIONAL INTERACTIONS WITH SERUM FACTORS. *(E.)* Koch, K.; Leffert, H. L. (Cell Biol. Lab., Salk Inst., San Diego, Calif.). *J. Cell Biol.* 62(3):780-791, 1974.

2745 STUDIES ON THE BIOGENESIS OF SMOOTH ENDOPLASMIC RETICULUM MEMBRANES IN HEPATOCYTES OF PHENOBARBITAL-TREATED RATS. II. THE SITE OF PHOSPHOLIPID SYNTHESIS IN THE INITIAL PHASE OF MEMBRANE PROLIFERATION. *(E.)* Higgins, J. A. (Yale Sch. Med., New Haven, Conn.). *J. Cell Biol.* 62(3):635-646, 1974.

2746 EFFECTS OF D-GALACTOSAMINE ON NUCLEOTIDE METABOLISM AND ON MICROSOMAL MEMBRANES IN MOUSE LIVER. *(E.)* Meszaros, K.; Antoni, F.; Mandl, J.; Hrabak, A.; Garzo, T. (Semmelweis Univ. Med. Sch., Budapest, Hungary). *FEBS Lett.* 44(2):141-145, 1974.

2784 BILE ACID INHIBITION OF INTESTINAL ANAEROBIC ORGANISMS. *(E.)* Binder, H. J.; Filburn, B.; Floch, M. (Dep. Intern. Med., Yale Univ., New Haven, Conn.). *Am. J. Clin. Nutr.* 28(2): 119-125, 1975.

The inhibitory effect of bile acids on *in vitro* growth of enteric anaerobic organisms was studied in fresh strains of intestinal bacteria isolated from stool cultures. Eleven strains of *Clostridia*, 15 of *Bacteroides*, 13 of *Lactobacillus*, and 12 of gram-negative enteric aerobes were used. The test media consisted of 3 ml each of bile acid or detergent solution and carbohydrate-free thioglycolate broth which was inoculated with an 18-hr broth culture of the test organism. Viable counts were made by quantitatively plating serial dilutions of the test cultures immediately and at 6-, 18-, or 34-hr intervals after the initiation of incubation. Unconjugated bile acids were immediately more effective in controlling the growth of enteric anaerobes than conjugated bile acids; the dihydroxy bile acids, chenodeoxycholic acid and deoxycholic acid, were more inhibitory than the trihydroxy acid, cholic acid. Greater inhibition was observed at pH 6.5 than at pH 7.5 but inhibition was prevented by the addition of lecithin to form mixed micelles. The inhibition by nonbile acid detergents and the failure of a nondetergent bile acid (dehydrocholic acid) to inhibit growth suggests that the mechanism of inhibition is related to the detergent properties of these bile acids. Growth of enteric aerobes was not inhibited by unconjugated bile acids. Although these studies have defined additional characteristics of intestinal anaerobe inhibition by bile acids, such as pH of the media and the presence of mixed micelles, the precise mechanism of this inhibition and potential physiological significance was not clearly established.

2785 THE MOVEMENT OF AN UNEMULSIFIED OIL TEST MEAL AND AQUEOUS- AND OIL-PHASE MARKERS THROUGH THE INTESTINE OF NORMAL AND BILE-DIVERTED RATS. *(E.)* Brand, S. J.; Morgan, R. G. H. (Dep. Physiol., Univ. West. Australia, Nedlands). *Q. J. Exp. Physiol.* 60(1):1-13, 1975.

The effect of bile diversion on gastric emptying and ileocecal transit was investigated by feeding an unemulsified oil test meal containing aqueous- and oil-phase markers (polyethylene glycol and ^{3}H-labeled triether) to control and bile fistula young male albino Wistar rats. Three groups of rats were used: Group I contained 17 internally bile-diverted rats; Group II contained 9 sham-operated animals; and Group III contained 16 control rats. Each rat was fed 0.5 ml of the test meal of unemulsified corn oil containing ^{3}H-labeled triether and ^{14}C-labeled triolein by gavage. The oil was immediately followed by 2 ml of a solution of 1% polyethylene glycol 4000 in 0.15 M NaCl. Rats were killed immediately or 2 or 4 hr after feeding and the gastrointestinal tract removed in 4 segments: stomach, proximal half of small bowel, distal half of small bowel, and cecum plus colon. The recovery of ^{14}C activity, ^{3}H activity (triether) and polyethylene glycol from each segment was calculated and expressed as a percentage of the dose fed. There was a close correlation between the recovery of triglyceride and triether at all levels of emptying, but triether was recovered in slight excess of triolein. There was a lower correlation between the gastric recovery of polyethylene glycol and ^{14}C-triglyceride; polyethylene moved ahead of the lipid phase in all groups. These results suggest that triether is a valid marker for following the movement of lipid through the bowel under the conditions of this study and that polyethylene glycol is of limited value as a marker. Triether:fat ratios indicated that fat absorption occurred largely from the upper small bowel in control animals and from the lower small bowel in the absence of bile. Bile diversion resulted in more rapid gastric emptying initially, but very slow gastric emptying of the last part of the test meal. Intestinal transit of test meal or either marker was not significantly affected by bile diversion. It is concluded that no evidence was found for a direct effect of bile diversion on gastrointestinal motility.

2786 EFFECT OF GASTROINTESTINAL HORMONES ON THE JEJUNAL AND ILEAL MUCOSA IN MICE AND HAMSTERS: HISTOPHYSIOLOGICAL STUDY. *(Fr.)*

Balas, D.; Senegas, F.; Frexinos, J.; Pradayrol, L.; Broussy, J.; Ribet, A. (Purpan Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 7:187-199, 1974.

After a 48 hr fast, mice and hamsters (mean age 3 months) received single i.p. injections of pentagastrin (3.6 or 12 μg/kg), secretin (1-10 U/kg), histamine (0.1-1 mg/kg), cholecystokinin-pancreozymin (CCK-PZ; 1-10 U/kg), cerulein (0.1-10 μg/kg), or serotonin (5-500 μg/kg) to determine the effects of these hormones on jejunal and ileal mucosa. While pentagastrin, secretin, and histamine had no appreciable effect on Paneth cells in either species, CCK-PZ, cerulein, and serotonin released zymogen granules from Paneth cells. CCK-PZ (doses of 2-3 U/kg) and cerulein (doses larger than 1 μg/kg) decreased the number of zymogen granules in Paneth cells 15-30 min after injection; this decrease was greater in hamsters than in mice. Between 60 and 90 min after injection, the number of zymogen granules increased again to levels above those in controls. While CCK-PZ (doses larger than 5 U/kg) increased the number of basal granules in mast cells in the crypts of Lieberkuhn in mice 30 to 75 min after injection, cerulein did not, even when administered in doses (10 μg/kg) larger than those needed to stimulate pancreatic and biliary secretion. Both CCK-PZ and cerulein stimulated maturation of granules in the Golgi apparatus. When administered in physiological doses, serotonin had no effect on Paneth cells, but at almost lethal doses (500 μg/kg) zymogen granules were rapidly released in both mice and hamsters. However, attempts to produce degranulation of Paneth cells *in vitro* with serotonin (10^{-6} to 1 mg/liter) were unsuccessful. Although these findings suggest that CCK-PZ and cerulein stimulate synthesis by increasing synthesis of granules in the Golgi apparatus, it cannot be ruled out that they act indirectly by stimulating production of pancreatic enzymes or bile. Large doses of serotonin may release zymogen granules by activating vagal centers; by producing a vagal effect locally by inhibiting cholinesterase, thus increasing accumulation of acetylcholine; and by increasing the frequency and amplitude of peristaltic activity, thus favoring the emptying and evacuation of secretion from intestinal glands.

2787 STIMULATION OF PROTEOLYTIC DIGESTION BY INTESTINAL GOBLET CELL MUCUS. *(E.)*

Shora, W.; Forstner, G. G.; Forstner, J. F. (Hosp. Sick Child., Univ. Toronto, Canada). *Gastroenterology* 68(3):470-479, 1975.

Intestinal goblet cell mucus from rat small intestine was added to incubations of casein and trypsin (or chymotrypsin) to determine whether mucus could inhibit proteolysis. Hydrolysis of α-casein by trypsin was used as a standard assay in the study. Goblet cell mucus stimulated casein hydrolysis, reaching a maximum effect at a mucus to casein ratio (w/w) of 0.083. Goblet cell mucus did not contain proteolytic enzymes or proenzymes as contaminants, nor did it serve as a substrate for trypsin. Stimulation was not reduced by removing 85% of the sialic acid from the goblet cell mucus. Pretreatment of casein by boiling and freezing decreased (50%) the goblet cell mucus effect, as did partial predigestion of casein by trypsin, and increasing trypsin concentration above 3 μg/ml. Goblet cell mucus also enhanced the hydrolysis by trypsin of intestinal brush border membrane protein, but had no effect on the hydrolysis of hemoglobin, albumin, or benzoyl arginine ethyl ester. It is suggested that goblet cell mucus interacts only with certain substrates (not the enzyme) to produce enhancement of trypsin hydrolysis.

2788 HYPERSENSITIVITY REACTIONS IN THE SMALL INTESTINE. I. THYMUS DEPENDENCE OF EXPERIMENTAL 'PARTIAL VILLOUS ATROPHY'. *(E.)*

Ferguson, A.; Jarrett, E. E. E. (West. Infirm., Glasgow, Scotland). *Gut* 16(2):115-117, 1975.

Small intestinal morphology was studied in thymus-deprived rats infected with *Nippostrongylus brasiliensis* to determine if the mechanism causing morphological changes could be immunological. Thymus-deprived Lister rats received whole-body irradiation and were infected between 1 and 3 months later with a s.c. injection of 4000 *N. brasiliensis* larvae. Six to 20 weeks after infection the animals were killed and sections of small intestine were prepared for histological study including measurements of villus height and crypt depth. Normal rats infected with *N. brasiliensis* showed crypt hyperplasia with villous atrophy in affected areas of the small intestine. In the thymus-deprived rats, the course of infection was prolonged, but the morphology appeared essentially normal in 70% of those animals. The findings suggest that the tissue damage associated with the *N. brasiliensis* infection is caused by a thymus-dependent immune reaction in the small intestine, and is not due simply to the toxic effects of the nematode.

2789 A ONE-STEP L-AMINO ACID OXIDASE ASSAY FOR INTESTINAL PEPTIDE HYDROLASE ACTIVITY.

(E.) Nicholson, J. A.; Kim, Y. S. (VA Hosp., San Francisco, Calif.). *Anal. Biochem.* 63(1):110-117, 1974.

A rapid 1-step assay for intestinal peptide hydrolase activity in mucosal homogenates, and in cytosol and particulate fractions prepared from homogenates has been developed. Mucosa from the proximal small intestine of male Wistar rats was used as the source of enzyme. Peptide hydrolysis, and estimation of liberated L-amino acids by use of L-amino acid oxidase, peroxidase, and a chromogen was achieved by a single incubation step. Each peptide was dissolved in 0.5 ml of 50 mM Tris-HCl, pH 8.0, and 1 ml of L-amino acid oxidase reagent (20 mg of L-amino acid oxidase, 2 mg of horseradish peroxidase, and 10 mg of *o*-dianisidine dissolved in 100 ml of Tris-HCl buffer pH 8.0) was added to these solutions. Tubes containing dipeptide substrate and L-amino acid oxidase reagent were maintained at 37 C and 25 µl of enzyme preparation was added. The reaction was stopped after a timed interval by addition of 0.74 ml 50% sulfuric acid, this amount giving optimal color development. Absorbance of the purple color was measured at 530 nm. The most suitable peptide substrates are dipeptides composed of 1 which does not react. Brush border peptide hydrolase activity may also be estimated with this assay by performing the incubation in the presence of *p*-hydroxymercuribenzoate. It is concluded that this method is simpler to perform than previously described 2-step methods and is especially useful in analyses of large numbers of samples.

2790 BILE SALT ALTERATION OF COLONIC ELECTROLYTE TRANSPORT: ROLE OF CYCLIC ADENOSINE MONOPHOSPHATE. *(E.)* Binder, H. J.; Filburn, C.; Volpe, B. T. (Dep. Intern. Med., Yale Univ., New Haven, Conn.) *Gastroenterology* 68(3):503-508, 1975.

The effect of bile salts on mucosal cyclic AMP (cAMP) levels and the effect of cAMP on ion transport were studied in rats. The cAMP content of the colonic mucosa of Sprague-Dawley rats was determined in two separate series of experiments during which mucosa was exposed to different bile salts under both *in vivo* and *in vitro* conditions. Colonic mucosal cAMP levels in the rat increased by 54% after *in vivo* incubation with taurochenodeoxycholic acid. Taurocholic acid, which neither induced fluid secretion nor increased short circuit current at concentrations at which taurochenodeoxycholic acid increased both, did not alter mucosal cAMP. Dibutyryl cAMP decreased net sodium absorption and increased short circuit current, findings which were qualitatively identical to those produced by taurochenodeoxycholic acid. These observations support the proposal that bile salts stimulate colonic electrolyte secretion by increasing mucosal cyclic AMP.

2791 RELATIONS OF WEAK-ELECTROLYTE TRANSPORT AND ACID-BASE METABOLISM IN RAT SMALL INTESTINE IN VITRO. *(E.)* Jackson, M. J.; Morgan, B. N. (George Washington Univ. Med. Cent., Washington, D.C.). *Am. J. Physiol.* 228(2):482-487, 1975.

The relations between the intestinal transport of weak electrolytes and the pattern of acid-base metabolism were studied in the rat small intestine *in vitro*. Tissue was taken from the jejunum and ileum of Wistar rats and used in two types of chamber preparations, one for the determination of weak-electrolyte fluxes and the other for studies of acid-base metabolism. Weak-electrolyte fluxes were estimated by the addition of 1mM benzoic acid or benzylamine to the incubation saline (kept at pH 7.3) and 0.5 µCi of ^{14}C-labeled tracer to one reservoir. The procedure used in the acid-base metabolism studies involved observation of pH changes in the mucosal and serosal fluids of the chamber system. The jejunal pattern of weak-electrolyte transport was net transport of weak acids from mucosal to serosal and of weak bases from serosal to mucosal; the pattern of acid-base metabolism was luminal acidification and serosal alkalinization. In the absence of sodium or in the presence of metabolic inhibitors, weak-electrolyte transport and serosal alkalinization were inhibited, but luminal acidification was not inhibited. The ileal pattern of weak-electrolyte transport was opposite that of the jejunum and could be associated with the presence of a luminal alkalinization process observed in that region. In the absence of chloride, the patterns observed in the ileum and jejunum were similar. The results confirm previous suggestions that the mechanisms for intestinal transport of weak electrolytes are related to asymmetries in the acid-base metabolism of the tissue.

2792 INTESTINAL LYMPH FORMATION AND FAT ABSORPTION: STIMULATION BY ACUTE ETHANOL ADMINISTRATION AND INHIBITION BY CHRONIC ETHANOL FEEDING. *(E.)* Baraona, E.; Lieber, C. S. (VA Hosp., Bronx, N.Y.). *Gastroenterology* 68(3):495-502, 1975.

The effects of both acute and chronic ethanol administration on the transport of dietary lipids into the lymph were studied in rats. To study the chronic effects of ethanol, rats were pair-fed liquid diets containing either ethanol (36% of calories) or isocaloric carbohydrate (control diet) for 3-4 weeks. The superior mesenteric lymph duct was cannulated and the accessory intestinal lymphatics were ligated. The acute effects of ethanol were assessed by comparing the response of the same animal to the randomized administration of ethanol, either in lipid emulsions administered intraduodenally or in liquid diets given by gastric tube. The acute administration of ethanol increased the flow of intestinal lymph and the output of proteins and dietary lipids into the lymph, primarily in the first hr after administration. During that time, the intraduodenal administration of ethanol (0.75 g/kg) without exogenous lipids increased the flow of lymph without changing the lymph lipid output. Stimulation of the lymph flow with neostigmine or by increasing the fluid load also enhanced the output of lymph proteins and the transport of exogenous lipids from the intestinal lumen into the lymph. The administration of an acute ethanol dose to rats chronically fed alcohol moderately increased the lymph flow but did not change the output of dietary lipids. Rats chronically fed alcohol responded to a dietary challenge devoid of ethanol with increases in both lymph flow and dietary lipid output, but the responses were smaller than in controls. The findings suggest that alcohol drinking may favor fat absorption temporarily, but the effect would tend to be abolished by prolonged ingestion of alcohol.

2793 PYRIMIDINE BIOSYNTHETIC ENZYMES IN RAT INTESTINE AFTER SMALL BOWEL RESECTION. *(E.)*

Nakayama, H.; Weser, E. (Univ. Texas Med. Sch., San Antonio). *Gastroenterology* 68(3):480-487, 1975.

Activities of the enzymes of pyrimidine biosynthesis were studied in rat intestine remaining after small bowel resection. Male Sprague-Dawley rats underwent resection of 50 cm of proximal or distal intestine or sham operation. At 1 and 6 months after surgery, aspartate transcarbamylase, dihydroorotase, and uridine kinase were assayed in whole mucosa and in crypt mucosa from the remaining intestinal segment. Determination of [^{3}H]thymidine incorporation into DNA was made 5 weeks after distal resection. In control bowel, enzyme activity was significantly greater in proximal compared with distal segments. One month after proximal or distal resection, mucosal weight and mucosal enzyme activity/cm of gut were greater in the remnant bowel compared with controls. There were no such differences at 6 months. Specific enzyme activity (including thymidine kinase) of isolated crypt mucosa was significantly increased 1 month after distal resection. In addition, [^{3}H]thymidine uptake into DNA of crypt mucosa from proximal remnants was also significantly increased. After small bowel resection, mucosal hyperplasia and an increase in nucleic acid synthesis and cell proliferation occur in the remaining segment, and the results indicate that the enzymes of pyrimidine biosynthesis also increase in the remaining bowel and parallel the accelerated rate of cell proliferation.

2794 DEOXYCHOLATE DEPRESSES SMALL-INTESTINE ENZYME ACTIVITY. *(E.)*

Gracey, M.; Houghton, M.; Thomas, J. (Princess Margaret Child. Med. Res. Found., Perth, Australia). *Gut* 16(1):53-56, 1975.

The effect of the deconjugated bile salt, sodium deoxycholate, on the activity of several small-intestine enzymes was studied in rats. Wistar rats were fed 25 mg sodium deoxycholate in their diet for 4 days; enzyme assays were done at 24-hr intervals following the bile salt feeding period. Oral administration of sodium deoxycholate caused depression of the activity of the small intestinal enzymes lactase, sucrase, maltase, alkaline phosphatase, and N-acetyl-β-glucosaminidase (a lysosomal enzyme). Alkaline phosphatase activity recovered rapidly and rose to above normal level within 24 hr after the animals resumed a normal diet. The activity of the three disaccharidases returned to normal within 7 days; there was no evidence of recovery of N-acetyl-β-glucosaminidase activity after 4 days of normal diet, and the degree of depression remained highly significant. The results show that sodium deoxycholate, when present in the lumen of the upper gut in excessive concentrations, may have harmful effects on intestinal digestive exzymes.

2795 MECHANISMS OF LIPID LOSS FROM THE SMALL INTESTINAL MUCOSA. *(E.)*

Waldram, R. (St. Thomas' Hosp., London, England). *Gut* 16(2):118-124, 1975.

Loss of lipids from the small intestinal mucosa was investigated by perfusion experiments in rats to show whether the loss is related to lipid solubility in the perfusion fluid. Wistar rats were prepared with a polyethylene cannula inserted into the small bowel. Perfusion fluids were 0.15 M NaCl/liter phosphate or glycine buffer solutions at pH 3.7, 5.4, and 9.7, with or without the addition of 5.7 or 11.4 mM taurocholic acid. Perfusates were extracted for estimation of DNA and for individual lipids (separated by thin-layer chromatography). No significant change in amounts of DNA or lipids was observed with time, with the exception of significantly more phosphatidyl choline in the first 11.4 mM taurocholic acid perfusion than in subsequent perfusates. Nor was there any significant difference in amounts of lipids or DNA in perfusates from fasted animals and those not fasted. Amounts of fatty acids were not related to DNA in any perfusion solution. The lipid compositions of mucosal cell suspensions and saline perfusates were found to be similar, except for fatty acids, which were found to be 18 times greater in the perfusates than in cell suspensions. The results suggest that free fatty acids reach the lumen by diffusion, that their solubility in the luminal fluid is a factor determining their rate of loss, and that triglycerides, cholesterol, phosphatidyl ethanolamine, and phosphatidyl choline are present only as the result of desquamation of mucosal cells.

2796 INTESTINAL METABOLISM OF PLASMA FREE FATTY ACIDS: INTRACELLULAR COMPARTMENTATION AND MECHANISMS OF CONTROL. *(E.)*

Gangl, A.; Ockner, R. K. (Univ. California Sch. Med., San Francisco). *J. Clin. Invest.* 55(4):803-813, 1975.

The metabolism of plasma free fatty acids in the intestinal mucosa of rats was investigated with particular regard to lipid absorption. [^{14}C]palmitic acid-rat serum complex was injected i.v. into Sprague-Dawley rats. Blood was collected at specified time intervals and the small intestine removed and prepared for analysis. Mucosal radioactivity was maximal 2 min after i.v. [^{14}C]palmitate. Of mucosal ^{14}C, 42% was in water-soluble metabolites, 28% in phospholipids, and 16% in triglycerides. The specific activity of mucosal triglyceride fatty acids was 11 times those of the serum, confirming *in situ* synthesis. Luminal fatty acids entering mucosa were chiefly esterified to triglycerides, while plasma free fatty acids were oxidized and incorporated into phospholipids. Mucosal metabolism of i.v. [^{14}C]palmitate was minimally affected by glucose administration; intraduodenal isocaloric ethanol inhibited mucosal oxidation of free fatty acids by 60% and nearly doubled their incorporation into triglycerides. During lipid absorption, mucosal uptake of plasma free fatty acids doubled and incorporation into intestinal lymph triglycerides was increased sixfold. Since similar activity was observed in both villi and crypts, it is suggested that the compartmentation of fatty acids is intracellular, that their metabolism in the epithelial cell appears to be determined by their site of entry into the cell, and in the fasting state plasma free fatty acids are both an energy source and a substrate for the synthesis of tissue phospholipid.

2797 CELLULAR ENZYMOLOGY OF THE HUMAN FOETAL INTESTINE. *(Fr.)* Tabbara, R.; Wegmenn, R. (French Fac. Med. Pharm., Beirut, Lebanon). *Ann. Histochim.* 19(1):77-83, 1974.

The activities of 32 enzymes were studied in the duodenum and jejunum of 4 human embryos, aged approximately 4 to 7.5 months. The activities of most enzymes were low at 4 months and increased with age. The exceptions were NADPH-tetrazolium réductase, lactate dehydrogenase, and peptidases which were highly active at 4 months, subsequently decreased, and later reached or exceeded their previous levels. Nucleic acids were present in large quantities throughout. However, at 4 months, no cell desquamation had occurred and nucleic acids were found in cells of the epithelium and chorion. After 7 months, desquamation was observed and meconium formed which contained large amounts of RNA and DNA. In general, metabolic activity was much lower in the chorion than in the epithelium. While variations in the activities of glucose-6-phosphatase, fructose-1,6-diphosphatase, lactate dehydrogenase, and glutamate dehydrogenase occurred in the epithelium, these variations were not found in the chorion.

2798 INFLUENCE OF SECRETIN AND CHOLECYSTOKININ ON MALTASE, SUCRASE AND LACTASE IN THE JEJUNUM OF THE RAT. *(E.)* Rommel, K.; Bohmer, R. (Dep. Clin. Chem., Univ. Ulm, Germany). *Digestion* 11(3/4): 194-198, 1974.

The activities of maltase, sucrase, and lactase were studied in rat intestinal mucosa, after injection of secretin or cholecystokinin. Wistar rats were fasted 12 hr and given either 1.5 U secretin or cholecystokinen i.v. Controls were given an equivalent volume of 0.9% saline. A segment of small intestine 20-40 cm from the pylorus was removed, the mucosa scraped off and the maltase, sucrase, and lactase activities determined. Maltase activity after secretin injection was 484.2 IU/mg protein as compared to a control value of 258.2 IU/mg protein. Sucrase activity was likewise raised from 62.1 to 121.5 IU/mg protein, while lactase activity was unaffected. Cholecystokinin caused no changes in any of the enzyme activities studied. It is concluded that there is a direct or indirect effect of secretin on synthesis or activation of maltase and sucrase.

2799 ANIMAL EXPERIMENTS ON METABOLIC CHANGES AND FECAL BILE ACID EXCRETION AFTER ILEAL RESECTION. *(Ger.)* Merkle, P.; Hartung, H.; Merkle, N.; Maurer, M. (Surg. Clin., Univ. Freiburg, Germany). *Bruns Beitr. Klin. Chir.* 221(8):638-642, 1974.

The distal half of the small intestine was resected, and a side-to-side anastomosis was made between the proximal stump of the small intestine and the cecum in 10 male and female rabbits. Blood samples were taken before surgery and at 2 week intervals thereafter for determination of Na^+, K^+, total protein, cholesterol, and triglyceride concentrations. Bile acid concentrations were determined on feces collected at the same times. Following administration of ^{131}I-labeled triolein, triglyceride absorption was measured 8 weeks after surgery. Serum electrolyte levels and triglyceride absorption remained unchanged after surgery, but serum triglyceride levels decreased slightly and cholesterol values by 50% 2-8 weeks after surgery. No change occurred in fecal bile acid excretion or in the consistency of the stools after surgery. These changes which differ greatly from those found in humans who have undergone ileectomy or who have ileal disease, indicate that resection of the distal small intestine in the rabbit does not increase bile acid synthesis or reabsorption. The decrease in serum cholesterol levels after enterectomy is attributed to decreases in cholesterol synthesis and absorption which normally occur in the small intestine.

2800 THE MORPHOLOGY AND ENZYME ACTIVITIES IN RAT SMALL INTESTINE DURING ORAL ADMINISTRATION OF NEOMYCIN AND GLIADIN-FREE AND GLIADIN-CONTAINING DIETS. *(Ger.)* Lucking, T. (Pediatr. Clin., Univ. Hamburg, Germany). *Z. Gastroenterol.* 13(2):362-367, 1975.

Of 40 male Wistar rats, 20 received a synthetic diet containing 5% gliadin, 15% casein, 65% sucrose, 15% corn oil, and a vitamin and mineral supplement while the remaining 20 were given a gliadin-free diet containing 20% casein. Starting 8 days later, 10 rats in each group received 12 mg/ml neomycin sulfate in their drinking water. After a 12 hr fast, rats were sacrificed 21 days later. All animals lost weight during the experiment. Those receiving neomycin lost more weight than controls, even those that also received gliadin. Neomycin-treated rats, both those given gliadin-free and gliadin-containing diets, showed much less spontaneous activity after 2 weeks of treatment than the controls. They ate and drank less so that their mean weights decreased from 150 g to 94.5 g in the group receiving gliadin and to 87.1 g in the group receiving the gliadin-free diet. Examination of the mucosa of the small intestine under a stereomicroscope showed no morphological differences between these four groups of rats. The activities of lactase, sucrase, maltase, glycyl-L-leucine dipeptidase, L-alanyl-L-leucine dipeptidase, acid and alkaline phosphatase, and β-glucuronidase, determined on supernatants from homogenized mucosa from the small intestine, were the same in all four groups of rats. From these results it is concluded that neomycin has some kind of toxic effect on rats although it causes no morphological or enzymatic changes in the small intestine.

2801 CHANGES IN DISACCHARIDASE ACTIVITIES IN THE SMALL INTESTINAL MUCOSA OF THE RAT AFTER A SINGLE DOSE OF 5-FLUOROURACIL. *(Ger.)* Mielke, F. (Charlottenburg Clin., Berlin, Germany). *Z. Gastroenterol.* 13(2):356-361, 1975.

A single dose of 40 mg 5-fluorouracil was injected i.p. into 70 female Wistar rats which were then sacrificed in groups of 10 each 24 to 168 hr later. This dose is 3 times that used therapeutically. Untreated rats served as controls. All animals were fasted for 24 hr before sacrifice. No gross morphological changes were found in the small intestine following administration of 5-fluorouracil. Disaccharidase activities, determined on homogenates of mucosa from the small intestine, were decreased after 48 hr: maltase activities by 13%, trehalase by 59%, lactase by 52%, and cellobiase by 61%. Except for maltase activities which reached a minimum 60 hr after injection, disaccharidase activities were lowest after 72 hr. At this time maltase activities were decreased by 40%, trehalase by 75%, lactase by 87%, and cellobiase by 94%. A significant increase in the activities of all enzymes occurred after 96 hr, but increased became more gradual thereafter. Even after 7 days, none of the enzymes had reached their initial levels. Maltase and trehalase activities were 4% and 10%, resp., below control values, while lactase and cellobiase were 26% and 28%, resp., lower. These findings, which agree with others in the literature, suggest that the first cell population covering the villi 96 hr after administration of 5-fluorouracil are not functionally mature. Absorption and digestion have almost normalized by the time the next cell population reaches the ends of the villi.

2831 RADIOMETRIC ESTIMATION OF THE AMOUNT OF SOLID GASTROINTESTINAL CONTENTS. *(E.)* Pfau, A.; Abadir, F. A. (Inst. Anim. Husb. Anim. Behavior, Mariensee, Germany). *Experientia* 30(11): 1296-1298, 1974.

The estimation of solid gastrointestinal contents by dilution techniques using radioactive markers was investigated in 12 78-week-old bulls. ^{152}Eu was used as the marker of the solid phase and ^{14}C-polyethyleneglycol (PEG) as marker of the liquid phase. The markers were administered in aqueous solutions *via* stomach tube or rumen fistula. Except for ^{14}C-PEG in ruminal fluid, all the other turnover rate constants for ^{152}Eu and ^{14}C-PEG in rumen or feces appeared to be almost identical. The solid phase in cattle gastrointestinal tract, therefore, could be described with a one-compartment model but at least two components are necessary to describe the fluid phase. These findings led to the conclusion that it is justified to use the ^{152}Eu fecal excretion measurements for determining the turnover rate of the ruminal solid phase even if other factors indicated different compartments to be assayed by fecal and ruminal estimates. Values obtained by this procedure *in vivo* demonstrated good agreement with gravimetric measurements after slaughter. The amount of dry matter in the intestine corresponded fairly well to the values from radiometric measurements on healthy bulls. It is suggested that ^{152}Eu dilution analysis might be of use for the estimation of the amount of solid contents in the intestine. However, without further measurements or assumptions, the wet content of the rumen or gastrointestinal tract cannot be obtained with this technique.

2832 EFFECT OF EXPOSURE TO HYPEROXIC, HYPOBARIC, AND HYPERBARIC ENVIRONMENTS ON CONCENTRATIONS OF SELECTED AEROBIC AND ANAEROBIC FECAL FLORA OF MICE. *(E.)* Gillmore, J. D.; Gordon, F. B. (Nav. Med. Res. Inst., Bethesda, Md.). *Appl. Microbiol.* 29(3):358-367, 1975.

Alterations in selected aerobic and anaerobic fecal microflora of the mouse were determined during exposure to hyperoxic and normoxic hypo- and hyperbaric environments. Examination of fecal cultures obtained during exposure of female NMRI Swiss mice for 6 weeks to 60 or 77% oxygen concentration at 1 atmosphere absolute revealed little alteration in the aerobic or anaerobic flora. There appeared to be only a retardation in the reduction of the *Klebsiella-Enterobacter* flora which normally occurs after weaning. During exposure to hypobaric environments (100% O_2, 0.2 atmosphere absolute), significant alteration (increases) in the concentrations of *Escherichia coli*, slow lactose fermenters, *Klebsiella-Enterobacter*, and enterococci were found in some instances. Variations in the concentrations of different colony types of obligately anaerobic gram-positive and gram-negative rods cultured during the same experiments also occurred. One colony type of gram-positive rods appeared to decrease, while a second type increased. The concentrations of three colony types of gram-negative rods were generally, but not always, increased. During hyperbaric exposure (2.8% O_2, 7.5 atmospheres absolute), increased concentrations of *Klebsiella-Enterobacter*, *E. coli*, slow lactose fermenters, and enterococci were noted. Changes in the numbers of both colony types of gram-positive rods, when occurring, were in the direction of lower numbers. Alterations in the numbers of gram-negative rods were in both directions but were more frequently in the direction of higher numbers. After return to normal air following 4 weeks of hypo- or hyperbaric exposure, the fecal concentrations of most organisms tended to revert toward control values; the gram-positive rods, however, remained in reduced concentrations. These data indicate that, despite the great variation in the fecal flora among individual mice, it is possible to discover the effects induced by altered gaseous environments.

2833 MECHANISM OF BLOODY DIARRHEA IN SHOCK. *(E.)* Crowell, J. W.; Nelson, Jr., K. M. (Univ. Mississippi Med. Cent., Jackson). *Circ. Shock* 2(1):21-28, 1975.

Ink was injected i.v. into anesthetized adult mongrel dogs to study the effect of shock on liver microcirculation. Prior to ink injection, the animals were subjected to hemorrhagic shock, hemorrhagic shock and hepatic artery occlusion, hepatic vein occlusion, or hepatic vein occlusion and portal diversion. In 10 normal control dogs, ink was evident after 3 hr from the triad to the central vein of the liver, although it was most dense in the triad area. After irreversible hemorrhagic shock, ink was still evident in the triad area but none was evident in the central vein area. Occlusion of the hepatic vein with the portal blood diverted into the femoral vein caused an ink pattern similar to that seen after hemorrhagic shock. Ligation of the hepatic artery after hemorrhagic shock resulted in a total absence of ink in large areas of the liver, with other areas showing ink in the same pattern observed in the controls. Hepatic vein occlusion without hemorrhagic shock resulted in an ink pattern similar to that seen in controls, but the ink was less dense. In the latter group, the liver was greatly enlarged. Portal blood by-pass resulting in the prevention of a high portal pressure prevented bloody diarrhea. The mechanism of bloody diarrhea in shock appears to be as follows. In low flow states, hypoxia causes swelling of the centrilobular liver cells with blockage of some of the sinusoids. The increase in portal resistance, the entrance of high pressure arterial blood into the portal system, and intestinal hyperemia all combine to cause a high portal pressure which destroys the intestinal mucosa and allows fluid and blood to enter the lumen; the result is bloody diarrhea.

2859 INCREASE IN THE QUANTITY OF METABOLIC FECAL NITROGEN IN THE RAT FOLLOWING INGESTION OF DIETS CONTAINING TANNIC ACID. *(Fr.)* Mitjavila, S.; Mitjavila, S.; Derache, R. (Inst. Physiol., Toulouse, France). *Ann. Nutr. Alim.* 28(3):189-198, 1974.

2860 ELECTROMYOGRAPHIC STUDY OF DIAPHRAGMATIC MOTOR ACTIVITY DURING VOMITING IN THE NON-ANESTHETIZED DOG. *(Fr.)* Monges, H.; Salducci, J.; Naudy, B. (Clin. Gastrointest. Dis. Nutr., Marseille, France). *Biol. Gastroenterol. (Paris)* 7(4):291, 1974.

DIAGNOSTIC PROCEDURES

2861 150 PANCREATIC SCINTIGRAPHIC ANALYSES. COMPARISON OF RADIOCLINICAL AND SURGICAL FINDINGS. *(Fr.)* Batisse, R.; Charbord, P. (Val-de-Grace Hosp., Paris, France). *Ann. Med. Interne (Paris)* 125(10):731-736, 1974.

Comparisons were made of clinical, biological, radiological, scintigraphic, and surgical findings on 89 patients. These patients had acute or chronic pancreatitis (25 cases), cancer of the pancreas (7), pancreatic shunts (3), obstructions of the papilla (2), primary adenocarcinoma of the liver (1), Zollinger-Ellison syndrome (1), and pancreatic ischemia caused by stenosis of the celiac trunk (1); 49 patients had no pancreatic abnormalities. Pancreatic scintigrams were obtained by double labelling with ^{75}Se-selenomethionine and ^{99m}Tc and subtraction of the liver scan. In all but 10% of these patients, accurate diagnoses were established from pancreatic scans. In patients with atypical abdominal pain, normal scans often made it possible to rule out chronic pancreatitis. The only exceptions were those with caudal lesions, which are difficult to detect and which are usually found in alcoholics at the onset of chronic pancreatitis. Scans from patients with caudal lesions were difficult to interpret because of the small size of the organ and because loops of jejunum or a hyperplastic left lobe of the liver, such as that found in alcoholics, were superimposed on the scan. In patients with acute pancreatitis, pancreatic scans confirmed the diagnosis based on clinical and biochemical findings. Lesions less than 2 cm in diameter, which were found in nodular pancreatitis and cancer, were not detected on pancreatic scans. However, cancer of the head of the pancreas was accompanied by readily detectable stasis in the pancreatic duct above the tumor.

2862 RAPID METHOD FOR DOUBLE CONTRAST RADIOGRAPHY OF THE COLON: UTILIZATION OF GLUCAGON. *(Fr.)* Hage, G. (St. Marguerite Hosp., Marseille, France). *Arch. Fr. Mal. App. Dig.* 63(4): 297-303, 1974.

A new method for obtaining double contrast x-rays of the terminal ileum and colon was used on 130 patients (58 females and 72 males, aged 5-93 yr; mean age 44 yr). Five hr before the x-ray examination, patients received an i.v. injection of 2 mg glucagon and 5 mg diazepam and a 4 liter enema which they held for 20-30 min while changing their position from left lateral decubitus to prone and then to right lateral decubitus. To evacuate any remaining water from the rectosigmoid, Normacol powder was administered 1 hr before the examination. With the patient in the left lateral decubitus, 250-300 ml of contrast medium (density 1.600) were administered, followed by gradual insufflation, with the patient in a prone position, until the contrast medium reached the cecum. The colon was then completely insufflated while the patient was rotated 2-3 times, and the x-ray examination was completed in an average of 10-15 min. The use of glucagon made it possible to obtain excellent double contrast patterns of the mucosa and to opacify the distal ileum. In all but 4 or 5 cases, the patients, including those with Crohn's disease of the colon and ulcerative colitis, tolerated the enema well. Although the enema was not properly administered in 12 cases, the examination had to be performed again in only 3. By means of double-contrast radiography, 24 organic lesions of the colon and terminal ileum were demonstrated. Of 10 patients with diverticula of the colon, 4 had isolated diverticula in the right colon, a finding which has not been reported before.

2863 MEASUREMENT OF CIRCULATING DESIALYLATED GLYCOPROTEINS AND CORRELATION WITH HEPATOCELLULAR DAMAGE. *(E.)* Marshall, J. S.; Green, A. M.; Pensky, J.; Williams, S.; Zinn, A.; Carlson, D. M. (Case West. Reserve Univ. Sch. Med., Cleveland, Ohio). *J. Clin. Invest.* 54:555-562, 1974.

The binding of human thyroxine-binding globulin to hepatic cell plasma membranes on desialylation was studied. The amount of [^{125}I]desialylated thyroxine-binding globulin (DTBG) bound to rat liver cell plasma membranes progressively increased on the addition of further desialylated glycoprotein, until a point at which the binding sites were apparently saturated. The results of inhibition assays in which purified unlabeled desialylated glycoprotein were preincubated with the membranes showed that unlabeled DTBG prevented the binding of approximately 90% of the [^{125}I]desialylated orosomucoid at a concentration of 2 μg/ml. Desialylated orosomucoid appeared to have a greater affinity than DTBG for the plasma membrane binding sites. Similarly, desialylated fetuin and desialylated ceruloplasmin bound less avidly than DTBG. In testing the serum from patients with a variety of illnesses, serum from patients with Laennec's cirrhosis, biliary cirrhosis, hepatic metastases, and alcoholism with a primary hepatoma demonstrated greatly increased inhibitory activity. However, four patients with jaundice secondary to common bile duct obstruction by tumor, one with ascites secondary to pancreatitis, another with abnormal liver function tests due to congestive heart failure, and two with markedly abnormal rheumatoid factor latex fixation tests had serum with inhibitory activity within the normal range. No simple correlation was found between serum inhibitory activity and levels of alkaline phosphatase, SGOT, total bilirubin, serum albumin, or serum globulin. Column chromatography on Sephadex G-200 of a sample of serum from a liver cirrhosis patient showed the expected reversal of albumin to globulin ration compared to normal serum. Results of this study indicate that the hormone transport protein, glycoprotein thyroxine-binding globulin, may now be added to the group of serum glycoproteins which, after desialylation, bind to liver cell membranes. As for the clinical importance of this inhibition assay, Laennec's cirrhosis, biliary cirrhosis, primary and metastatic liver carcinoma, and hepatitis appear to be associated with elevated levels of circulating desialylated glycoproteins. Patients with abnormal liver function tests due to congestive heart failure, pancreatitis, or extrinsic biliary tract obstruction had normal inhibitory activity.

2864 D-XYLOSE ABSORPTION TEST AND QUANTITATIVE IMMUNOGLOBIN DETERMINATION AS SELECTION CRITERIA FOR PERFORMING PERORAL ASPIRATION BIOPSIES OF THE SMALL INTESTINE. *(Ger.)* Tinschmann, P.; Bertholdt, F. (Pediatr. Clin., Univ. Dusseldorf, Germany). *Monatschr. Kinderheilk.* 122(7):575-577, 1974.

Peroral biopsies and xylose tests were performed on 60 children, aged 6 weeks to 4 yr, who were suspected of suffering from malabsorption. Total atrophy of the villi was found in 16 biopsies. The data were categorized as either concordant or discordant and were evaluated for (1) length of time between the 2 tests (with the xylose test always preceding the biopsy) and (2) length of diet therapy before the first test. When tests were performed 0 to 10 days apart, results agreed on 75%; for a period of 11 to 21 days, only 47% agreed. After 0 to 10 days of diet therapy, results agreed in 80%, while after diet therapy for 11 to 21 days, only 18% agreed. Agreement after 21 days of therapy increased again to 78%. This suggests that the absorption of the mucosa responds more quickly to treatment than do morphological changes in the mucosa. Immunoglobulin determinations, performed in 38 cases, showed that patients with mucosal atrophy had IgA levels significantly higher than normal. Results from the D-xylose test and biopsy agree if both are performed simultaneously before institution of therapy. Celiac disease can be diagnosed with a high degree of accuracy in patients with decreased D-xylose absorption and increased IgA levels.

2865 EVALUATION OF FOUR VARIANTS OF THE INDIRECT HEMAGGLUTINATION TEST FOR HUMAN HYDATIDOSIS. *(E.)* Varela-Diaz, V. M.; Lopez-Lemes, M. H.; Prezioso, U.; Coltorti, E. A.; Yarzabal, L. A. (Pan Am. Zoonoses Cent., Panam. Health Organ./World Health Organ., Buenos Aires, Argentina). *Am. J. Trop. Med. Hyg.* 24(2):304-311, 1975.

The comparative sensitivity and specificity of the tannic acid, glutaraldehyde, benzidine and formol indirect hemagglutination test (IHA) were evaluated in the immunodiagnosis of human hydatidosis. Using the same pool of hydatid cyst fluid, 74 hydatosis sera were examined by each of the four IHA techniques. When the criterion for IHA test positivity was based on the observation of hemagglutination titers of 1:32 and above, the comparitive sensitivity of the four tests was found to vary with the group of sera examined. The highest titer at which hemagglutination was observed in non-hydatid sera was 1:32 with tannic acid, 1:256 with glutaraldehyde, and 1:128 with benzidine and formol-treated cells. Both the sensetivity and non-specificity of each IHA test variant was higher when the positivity criterion was based on the detection of reactors than when only titers were considered. The low rate of nonspecific reactions and higher sensitivity of the tannic acid IHA test, based on a diagnostic titer for hydatidosis as positivity criterion, suggest that it is more effective than the glutaraldehyde and benzidine tests.

2866 PREOPERATIVE CYTOLOGICAL DIAGNOSIS OF GASTRIC LEIOMYOSARCOMA. A REPORT OF THREE CASES. *(E.)* Cabre-Fiol, V.; Vilardel, F.; Sala-Cladera, E.; Perez Mota, A. (Santa Cruz San Pablo Hosp., Barcelona, Spain). *Gastroenterology* 68(3): 563-566, 1975.

The cytological characteristics of three recent cases of gastric leiomyosarcoma in which the diagnostic cells were obtained by an endoscopic cytology technique are described. Previous radiological diagnoses were malignant ulcer in one case, probable benign ulcer in one case, and multiple benign tumors in the third case. The diagnostic cells were obtained by exfoliative cytology using a brushing technique under direct vision. Malignant cells, mostly spindle-shaped, were found isolated or forming small groups. The cells had very elongated, clear cytoplasm with no vacuoles. The nuclei were hypertrophic, ovoid, and sometimes rounded. Chromatin distribution in the nuclei was irregular and in some instances the nuclei appeared segmented. Occasionally, malignant cells contained several, small superimposed nuclei with thick nuclear membranes and prominent nucleoli. Some such cells resembled epidermoid tadpole cells, while others featured an extremely long, fiber-like cytoplasm. These cells were interspersed with large, undifferentiated malignant cells. Sheets of cells from the superficial columnar epithelium were found in all smears; many exhibited signs of chronic gastritis. In two cases, gastroscopic biopsies showed normal superficial epithelium, and in the third case, several biopsy specimens showed malignant tissue. The definitive histological diagnosis in all cases was gastric leiomyosarcoma. The superiority of cytology over biopsy in this group of tumors may be explained in part by the submucosal growth of leiomyosarcoma, which prevents adequate biopsies, and in part by the wider area of samples of abrasive techniques under direct vision.

2867 ULTRASONICALLY GUIDED PERCUTANEOUS FINE NEEDLE BIOPSY OF THE PANCREAS. *(E.)* Hancke, S.; Holm, G. G.; Koch, F. (Gentofte Hosp., Hellerup, Denmark). *Surg. Gynecol. Obstet.* 140(3): 361-364, 1975.

A new method for the preoperative demonstration of malignant conditions of the pancreas is presented and preliminary results using it reported. By ultrasonic scanning of the abdomen, cross-sectional views of the organs, including the pancreas, can be outlined on an oscilloscope screen; lesions may thereby be demonstrated providing they have a certain minimum size. When a lesion is outlined, a guided puncture can be performed with a special ultrasonic transducer; the needle will follow exactly the direction of the sound beam emitted from the transducer. The ultrasonic scanning is performed with the patient in the supine position. When the lesion is located, the optimal place for the puncture is marked on the skin. The depth of the lesion is read from the oscilloscope screen and is marked on the fine needle. Aspirations are performed according to the technique described by Franzen. Routinely, 4 to 6 punctures in various directions are performed through the same guide cannula. Between July 1973 and September 1974, ultrasonic investigation was performed in about 410 patients, of whom 80 were found to have pancreatic disease. In 36 patients with suspected pancreatic lesions, scanning demonstrated a solid mass lesion in the pancreas; 21 biopsied patients had carcinoma and four had chronic pancreatitis. In 17 of the carcinoma patients, tumor cells were aspirated; the cells were numerous and easily recognizable, fulfilling the cytologic criteria of malignant disease. Aspirations could not be adequately performed in three carcinoma patients and normal pancreatic cells were aspirated from a fourth. In the four patients with chronic pancreatitis, normal pancreatic cells were aspirated. There were no immediate complications due to fine needle biopsy. The combination of ultrasonic scanning and ultrasonically guided percutaneous fine needle aspiration is an important adjunct to the management of pancreatic lesions, although more investigation is needed regarding the diagnostic sensitivity of the scanning technique and the cytologic evaluation of the aspirates.

2868 DIAGNOSIS AND PROGNOSIS IN COLON CANCER BASED ON A PROFILE OF IMMUNE REACTIVITY. *(E.)* Lurie, B. B.; Bull, D. M.; Zamcheck, N.; Steward, A. M.; Helms, R. A. (Boston City Hosp., Mass.). *J. Natl. Cancer Inst.* 54(2):319-325, 1975.

An immunologic profile consisting of measurements of circulating carcinoembryonic antigen (CEA), tumor antigen-induced inhibition of mononuclear cell migration (IMM), and skin reactivity to purified protein derivative, streptokinase-streptodornase, and mumps was assessed in 16 patients (4 female) with colon cancer. Before surgery, 10 of 14 patients tested had elevated CEA levels, 12 of 12 showed positive IMM, and 10 of 11 failed to react to two or more recall skin-test antigens. Among seven patients whose tumor were limited to the bowel wall and presumably completely removed at surgery, CEA assays either remained negative or became negative during the first month after surgery. Elevated CEA levels later occurred in three patients, none of whom showed evidence of recurrent colon cancer. All seven patients showed negative IMM tests 2 or more months after surgery, and increased skin-test reactivity was seen in six patients 3 or more months after surgery. One patient with a negative reaction in all skin tests had rising CEA values. In nine patients whose tumor masses were not completely removed at surgery, all had elevated CEA levels within a short time after surgery, none showed tumor antigen-induced IMM, and six showed suppressed skin-test reactivity. CEA, IMM, and skin test results remained unchanged in three patients with nonmalignant lesions. Used separately, CEA, IMM, and skin reactivity to recall antigens have known limitations, but the combined use of all three improves diagnosis and prognosis in colon cancer patients.

2869 PAROTID SALIVA TEST COMPARED WITH PANCREOZYMIN-SECRETIN TEST IN DIAGNOSIS OF PANCREATIC DISORDERS. *(E.)* Kakizaki, G.; Saito, T.; Soeno, T.; Sasahara, M.; Ohizumi, T.; Kato, E.; Fujiwara, Y. (Akita Univ. Med Sch., Japan). *Tohoku J. Exp. Med.* 114(3):241-245, 1974.

The pancreozymin-secretin and the parotid saliva tests were compared with regard to their reliability as diagnostic tools for pancreatic disorders in 12 patients with pancreatic disorders and 10 with non-pancreatic disorders. Both tests gave fairly comparable results in the group of patients with pancreatic disorders. The parotid saliva test gave false negative results for 1 of 3 patients with cholecystolithiasis with satellite pancreatitis, whereas the pancreozymin-secretin gave negative results for all three patients. In one patient with cancer of the head of the pancreas the pancreozymin-secretin test gave more reliable results than the parotid saliva test. The parotid saliva test was negative in all patients with non-pancreatic disorders, while the pancreozymin-secretin gave false positive results in eight of 10 patients. Positive results of the pancreozymin-secretin test were 75% accurate and those of the parotid saliva test were 83.3% accurate in the 12 patients with pancreatic disease. In 10 patients with non-pancreatic disorders, the parotid saliva test was 100% accurate, while the pancreozymin-secretin test gave very high false positive results. As a whole, a positive parotid saliva test was 90.9% accurate in diagnosing pancreatic disorders, while a positive pancreozymin-secretin test was only 50% accurate. It is suggested that the parotid saliva test is a potentially useful test in predicting the presence or absence of pancreatic disorders regardless of the presence of abnormal biliary function or of duodenal disease.

2870 USE OF THE ENTEROTEST DUODENAL CAPSULE IN THE DIAGNOSIS OF GIARDIASIS. A PRELIMINARY STUDY. *(E.)* Thomas, G. E.; Goldsmid, J. M.; Wicks, A. C. B. (Dep. Med., Univ. Rhodesia, Salisbury). *S. Afr. Med. J.* 48(53):2219-2220, 1974.

The Enterotest capsule was compared with stool examination and jejunal aspirate as a method for finding *Giardia lamblia* in patients under investigation for malabsorption as a cause of megaloblastic anemia. The Enterotest consists of a gelatin pharmaceutical capsule lined with silicone rubber in which is embedded a 1 g spherical lead weight. Packed inside the capsule is 140 cm of thread and 3-ply white nylon yarn with the free end protruding through a hole in one end of the capsule. When the capsule is swallowed, the free end of the yarn is attached to the patient's mouth. The gelatin dissolves in the stomach leaving a small lead-weighted rubber bag which passes through the pylorus. When the yarn is withdrawn, it leaves the rubber bag to pass in the stool. The mucus which adheres to the yarn is scraped off and examined microscopically for parasites. The Enterotest was positive 5 of 6 times and the jejunal aspirate from the Crosby capsule 4 of 7 times. The first stool was positive twice and the second stool twice; in two patients three consecutive stools were negative. It is concluded that the Enterotest is a safe and effective technique for screening patients for upper gastrointestinal parasites and appears to be more useful than stool and biopsy examination.

2871 RADIOMANOMETRY IN THE DIAGNOSIS OF COMMON BILE DUCT DISEASE. *(E.)* Mieny, C. J.;

Mendelow, D.; Cooke, P. (J. G. Strydom Hosp., Johannesburg, South Africa). *S. Afr. J. Surg.* 12(4): 189-191, 1974.

Pressure and flow measurements were made during biliary surgery in 44 cases. An 8 F.g. feeding tube was inserted through the cystic duct into the common duct and a standard cholangiogram was performed. The barrel of a 20 ml disposable syringe was then connected to the tube and filled with saline. The barrel was raised beside a vertical ruler and opening pressure recorded when the level began to drop. Flow rate per min was recorded at opening pressure and at 30 cm. In 28 cases presenting with stones in the gallbladder but normal common ducts, opening pressure was 14 cm saline, and flow rate 25 ml/min at 30 cm. In 12 cases with stones in the common duct, opening pressure was 28 cm, and flow rate 14 ml/min. In four miscellaneous cases (two pancreatitis, one common bile duct carcinoma, one dilated common bile duct) opening pressure was 23 cm and flow rate 13 ml/min. It is concluded that when opening pressure is over 20 cm, exploration of the common bile duct is indicated.

2872 SEPTIC COMPLICATIONS FOLLOWING ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY. *(E.)* Davis, J. L.; Milligan, F. D.; Cameron, J. L. (John Hopkins Med. Inst., Baltimore, Md.). *Surg. Gynecol. Obstet.* 140(3):365-367, 1975.

Four cases of septic complications resulting from retrograde cholangiography and pancreatography are presented. In each case, pyrexia and usually abdominal pain appeared within 48 hr after the procedure. Stasis was present in each of the cases, but was unlikely in itself to have been sufficient cause. Infection may have been due to cannulation by introduction of bacteria, or by dissemination of already contaminated bile. In each case immediate surgery was performed, and recovery was successful in all but one patient, who had diffuse metastatic carcinoma of the liver. It is suggested that early operative intervention be planned for any patient in whom the procedure demonstrates stasis. The abdomen should be x-rayed 12-24 hr after the procedure to check for retained contrast media. Any patient developing abdominal pain and fever not responsive to antibiotics, fluid therapy or nasogastric suction should undergo immediate laparotomy. Finally, it is suggested that all patients undergoing this procedure be given antibiotic treatment.

2873 ANGIOGRAPHY OF GALLBLADDER CANCER. *(E.)* Kido, C.; Hibino, K.; Kaneko, M.; Sasaki, T. (Aichi Cancer Cent. Hosp., Japan). *Nippon Acta Radiol.* 34(1):1-11, 1974.

Selective angiography was evaluated in the diagnosis of gallbladder cancer. Twenty-five cases presenting with either a palpable tumor in the right hypochondrium, or jaundice, or both were studied. The cystic artery showed vasodilation in 17 cases (68%), hypervascularity in 20 cases (80%), and tumor-stain in 16 cases (64%). These blood vessels showed luminal irregularity and stiffening in 64%, displacement or interruption due to gallbladder swelling in 32%, slight displacement to the left of the gastroduodenal artery in 44% and stenosis or interruption of the gastroduodenal artery or proliferation of minute blood vessels in 12%. On histological examination, adenocarcinoma was found in 17 cases, papillary adenocarcinoma in two, anaplastic carcinoma in four, and mucoepidermoid and leiomyosarcoma in one case each. Liver metastasis was angiographically observed in 12, and liver cirrhosis in four cases. Gallbladder cancer was successfully diagnosed by angiography in 18 of 25 cases (72%). It is concluded that angiography provides a high rate of successful diagnosis, and is superior to other methods previously employed.

2874 THE BUDD-CHIARI SYNDROME: CORRELATION BETWEEN HEPATIC SCINTIGRAPHY AND THE CLINICAL, RADIOLOGICAL, AND PATHOLOGICAL FINDINGS IN NINETEEN CASES OF HEPATIC VENOUS OUTFLOW OBSTRUCTION. *(E.)* Tavill, A. S.; Wood, E. J.; Kreel, L.; Jones, E. A.; Gregory, M.; Sherlock, S. (R. Free Hosp., London, England). *Gastroenterology* 68(3): 509-518, 1975.

Between 1965 and 1972, 19 patients (12 female) with proven hepatic venous outflow obstruction were studied and the abnormalities observed on hepatic scintigraphy correlated with those seen on vascular radiology. In 10 cases, hepatic venous occlusion was secondary to other disorders, the most common being polycythemia rubra; in the remaining nine patients, no underlying cause for the hepatic venous occlusion was found. Serum albumin was reduced below normal levels in 12 patients, serum bilirubin was raised in 16 patients, and serum alkaline phosphatase was frequently raised although seldom excessively. Liver biopsies showed varying degrees of venous congestion, hemorrhage, and necrosis. In 15 patients, hepatic scintigraphy showed central localization of radiocolloid, this being the predominant feature in seven patients; normally, the maximum uptake is to the right of the midline. The inferior vena cava showed some degree of narrowing or distortion in its intrahepatic course in 13 patients, was occluded in three, and appeared normal in two. All but one patient showed a raised inferior vena cava pressure. Presumptive evidence of complete occlusion of the main hepatic veins was found in five patients; in nine others, a variety of venographic findings were demonstrated. Celiac axis arteriography showed stretching, arching, and attenuation in the intrahepatic arteries. Seventeen patients deteriorated progressively, the period between onset of symptoms and death ranging from 6 weeks to 3.5 yr. Ascites was a major problem in all but one patient. In six cases, autopsy revealed disproportionate enlargement of the caudate lobe, and in seven, the main hepatic veins were occluded by fibrous stenosis or organized thrombus. Additional studies indicated that the separate venous drainage of the caudate lobe may be preserved when the main hepatic veins are occluded and that hypertrophy of the caudate lobe occurs because of its relatively more efficient perfusion. Demonstration of the enlarged caudate lobe by scintiscanning and inferior vena cavography provides valuable diagnostic support for the Budd-Chiari syndrome.

2875 SERUM FERRITIN IN PATIENTS WITH IRON OVERLOAD AND WITH ACUTE AND CHRONIC LIVER DISEASES. *(E.)* Prieto, J.; Barry, M.; Sherlock, S. (R. Free Hosp., London, England). *Gastroenterology* 68(3):525-533, 1975.

Serum ferritin concentrations in patients with acute and chronic liver disease were studied by immunoradiometric assay, and the test was evaluated as a measure of storage iron. Included were 11 patients with idiopathic hemochromatosis, one hematologically normal subject who had received iron-dextran i.m. over a 2-yr period, 20 patients with iron overload from hematological disease, 13 patients with acute non-alcoholic liver disease, 24 patients with alcoholic liver disease, 19 patients with cryptogenic cirrhosis, 11 with primary biliary cirrhosis, 28 normal controls, and five with chronic simple iron deficiency anemia. Serum ferritin showed a significant correlation with liver iron concentration in idiopathic hemochromatosis and in iron overload from hematological disease. In six patients with untreated hemochromatosis, serum ferritin levels of 1290-8300 μg/liter were found. In two of three patients with idiopathic hemochromatosis, the serum ferritin fell during phlebotomy therapy in an inverse exponential relationship with the cumulative amount of storage iron removed, but the rate of fall increased toward the end of the treatment as the ferritin levels became normal and sub-normal. In all three, liver iron concentration was high; hemosiderin granules were present in the portal tract and perilobular fibrous tissue, but only trace amounts of iron were found intracellularly. Ferritin levels were high in patients with acute and chronic liver disease, the highest values (over 27,600 μg/liter) in patients with viral and drug-induced hepatic necrosis. Although high ferritin levels were associated with severe or active hepatocellular disease, regardless of etiology, not all patients with increased transaminase values had high ferritin. Women and patients with recent hemorrhage tended to have lower ferritin levels. In patients with hepatocellular disease of rapidly changing activity, serum transaminase level changes were accompanied by proportional changes in serum ferritin. There was also a significant correlation between serum ferritin and aspartate transaminase in 63 patients, but this disappeared when the patients with ferritin levels above 1200 μg/liter were omitted. It is concluded that the ferritinemia of liver disease may be largely derived from damaged hepatocytes, and that serum ferritin measurement is an ideal way of monitoring the progress of idiopathic hemochromatosis patients during treatment.

2876 AMYLASE CLEARANCE IN DIFFERENTIATING ACUTE PANCREATITIS FROM PEPTIC ULCER WITH HYPERAMYLASEMIA. *(E.)* Warshaw, A. L.; Lesser, P. B. (Massachusetts Gen. Hosp., Boston). *Ann. Surg.* 181(3):314-316, 1975.

Patients (34) with abdominal pain, tenderness, and hyperamylasemia suggestive of acute pancreatitis were studied prospectively to elucidate the relationship between peptic ulcer disease and pancreatitis. The admitting diagnosis in each case was pancreatitis. The first group of 25 patients had a protracted course of illness consistent with acute pancreatitis as well as evidence of pancreatitis either on upper gastrointestinal series or at surgery. Seven patients (Group II) had rapid resolution of pain and had no evidence of pancreatic inflammation rather than high serum amylase and epigastric tenderness. The diagnosis of nonperforated peptic ulcer disease without concomitant pancreatitis was made both radiologically and at surgery in four patients and by upper gastrointestinal series alone in three. Two patients (Group III) had duodenal ulcers demonstrated by upper gastrointestinal series and signs of pancreatic swelling and inflammation. All patients had significantly elevated serum amylase, and the three diagnostic groups did not differ in urinary amylase, serum lipase, serum calcium, or white blood count. The amylase:creatinine clearance ratio was 3-fold higher than normal in the first and third groups, but normal in the second; there was very little overlap of the ranges for patients with and without pancreatitis. The amylase:creatinine clearance ratio is therefore useful for confirming or questioning the diagnosis of acute pancreatitis. Patients with normal clearance ratio should be evaluated immediately for other conditions which cause hyperamylasemia, including gastric or duodenal ulcer.

2877 REAPPRAISAL OF ENDOSCOPIC TISSUE DIAGNOSIS IN SECONDARY GASTRIC LYMPHOMA. *(E.)* Posner, G.; Lightdale, C. J.; Cooper, M.; Sherlock, P.; Winawer, S. J. (Mem. Sloan-Kettering Cancer Cent., New York, N.Y.). *Gastrointest. Endosc.* 21 (3):123-125, 1975.

A reappraisal of the ability of endoscopy to document the presence of gastric involvement in disseminated lymphoma is presented. Charts of 14 patients (seven female) with proven gastric lymphoma who had been endoscoped were reviewed. The reasons for endoscopy included upper gastrointestinal bleeding, abdominal mass, abdominal pain, and evaluation of the extent of disease in patients previously diagnosed . Ten of the patients had tissue diagnosis made at endoscopy, and in four patients, attempts to make an endoscopic diagnosis failed. In all patients a malignant neoplasm of unknown type was diagnosed by endoscopic visualization. Large, thickened folds were seen in 10 patients, and the folds appeared nodular in three additional patients. In one patient with reticulum cell sarcoma, there was rigidity and a malignant-appearing ulcer, and in one patient with Hodgkin's disease there was an ulcerated mass. Endoscopic cytological washings did not add to biopsy and directed brush cytology in obtaining malignant tissue. The results indicate that with current endoscopes and directed biopsy and cytology techniques, there is a good likelihood of obtaining a tissue diagnosis in gastric lymphoma. In cases where gastric lymphoma is suspected, an aggressive attempt to confirm the diagnosis using these techniques is suggested.

2878 COMPARISON OF GASTRIC SECRETION STIMULATED BY HISTAMINE IN CONTINUOUS INFUSION AND IN A SINGLE SUBCUTANEOUS DOSE. *(Sp.)* Chahud, I. A.; Zegarra, A. C.; Bouroncle, C. J. M. (Hipolito Unanue Hosp., Lima, Peru). *Rev. Esp. Enferm. Apar. Dig.* 44(2):131-140, 1974.

A comparison was made between the augmented histamine test and the histamine infusion test in 16 patients. For the augmented histamine test, basal values for volume, acidity, and acid output were measured every 15 min for 1 hr. Patients received 10 mg of chlorpheniramine maleate i.m. 30 min before a single s.c. injection of 0.04 mg/kg histamine phosphate. The histamine infusion test, performed 48 hr later, consisted of slow i.v. infusion of 0.04 mg/kg. histamine and measurement of volume, acidity, and acid output after basal values had been obtained. In the histamine infusion test, values for volume and acidity were higher and remained almost constant at a high level, while in the augmented histamine test these values increased within 15 min after administration of histamine and then, 45 min after injection, began to decrease. Better values for maximum acid output were also obtained with the histamine infusion test. Values of 18.757 and 18.757 mEq/hr were obtained for the 1st and 2nd hr after histamine infusion, in comparison to 14.031 and 10.031 mEq/hr, resp., obtained with the augmented histamine test. The difference between these results was significant, as was that for 15 min fractions. The side effects of histamine were less severe and less disagreeable when histamine was infused rather than injected s.c. The histamine infusion test is recommended for patients with hypochlorhydria and for evaluating the results of vagotomy.

2879 DOUBLE CONTRAST EXAMINATION OF THE STOMACH AS A PART OF ROUTINE DIAGNOSIS. *(Ger.)* Tschaikowski, K. L. (no affil.). *Leber Magen Darm* 4(4):158-164, 1974.

A technique has been developed by which double-contrast x-rays of the stomach can be obtained without insufflating the stomach with air. The patient is given hexocyclium methyl sulfate the evening before the examination to reduce gastric secretion and N-butylscopolammonium bromide s.c. 15 min before to reduce gastric motility and muscle tonus. The patient then receives 100 ml of contrast medium (Unibaryt C) to which a teaspoon of a special emulsion has been added to prevent gas bubbles and improve adhesiveness of the contrast medium. Paspertin (25 drops) is also added. The concentration of Unibaryt C should be higher than that recommended on the package. It is recommended that 3.4 parts of contrast medium be used to 1 part water. After this, the patient drinks an effervescent powder (tartaric acid and sodium bicarbonate, 1:1). After 3-5 min, the patient is positioned on his left side with his head lowered. If the stomach contains much fasting secretion or is very relaxed, 50-100 ml of normal contrast medium are administered. X-rays are then taken as with the double contrast method. The relief of the gastric mucosa shows up best when 70-90 kV are used.

2880 VALUE OF ARTERIOGRAPHY IN THE DIAGNOSIS OF CANCER OF THE GALL BLADDER. *(Fr.)* Coulomb, M.; Marty, F.; Baudin, P.; Aguettaz, G.; Geindre, M. (Univ. Hosp. Cent. Grenoble, France). *Ann. Radiol. (Paris)* 17(5):497-505, 1974.

The technique of celiac-mesenteric arteriography was evaluated in the diagnosis of 4 patients with gallbladder cancer. In three cases, arteriography supported the diagnosis of cancer of the gall bladder, while laparoscopy produced a conclusive diagnosis in only one case. In one case, a definitive diagnosis of gallbladder cancer was only made on operation, although reexamination of the arteriographic evidence after the fact showed clear signs of a malignant gallbladder tumor. Arteriographic evidence for gallbladder cancer included dilation of the cystic artery (in three of the four cases); parietal invasion or amputation of the cystic branches (in three cases); anarchic neovascularization (three); tumorography (four cases); abnormal venous return (two); signs of hepatic invasion (four cases); and loco-regional extension into the duodenopancreas, colon and venous portal system (one case). In this series, surgery was contraindicated in two cases. Contraindications included massive hepatic invasion, duodenopancreatic extension, and complete obstruction of the portal vein. The extent of the lesions and the feasibility of surgery can thus be assessed by means of angiography.

2881 RADIOLOGICAL SIGNS OF ILEOCOLIC INVAGINATIONS IN ADULTS: THIRTEEN CASES. *(Fr.)* Bret, P.; Piante, M.; Tran Minh, V.; Deliot, J. F. (Edouard-Herriot Hosp., Lyon, France). *Ann. Radiol. (Paris)* 17(5):471-477, 1974.

Ileocolic invagination was observed in 13 patients, aged 51-81 yr. The patients had presented with digestive hemorrhage, difficulty in intestinal transit, and pain. There were seven instances of cancer, including four epitheliomas and three sarcomas; four cases of benign tumors, including one adenoma and three lipomas; and two cases requiring no surgical intervention which appeared from the radiological evidence to be benign. Interpretation of the radiological evidence is facilitated when the obstruction is not complete. The picture of ileocolic invagination is characterized by segmentary enlargement of the caliber of the colon, absence of fill-in of the dilated segment accompanied by a lacunary image, and specific characteristics of the lacunary image. Diagnosis of the benign or malignant nature of the tumor was possible radiologically in 2/3 of the cases. When the radiological evidence of a barium enema does not suffice, an intestinal transit should resolve doubts by identifying a slowing of the duration of transit in cases of intestinal stenosis; ascension of the ileocecal region; migration and infundibular aspect of the section; and generally satisfactory impregnation of this section contrasting with the lacunary image.

2882 PANCREATITIS: THE PANCREATOGRAM AND EXOCRINE PANCREATIC FUNCTION. *(Ger.)* Loffler, A.; Stadelmann, O.; Wobser, E.; Miederer, S. E. (Med. Polyclin., Univ. Bonn, Germany). *Leber Magen Darm* 4(5):195-200, 1974.

Endoscopic retrograde pancreatography and the secretin-pancreozymin test were performed on 46 patients who were recovering from acute or acute recurrent pancreatitis or who had clinically diagnosed pancreatitis or pancreatic calcification. Radiological findings were grouped into four stages: (0) no pathological changes; (1) circumscribed dilatations of the duct, isolated stenosis, and/or circumscribed or generalized parenchymal opacification which, in some cases, was associated with small cysts; (2) moderate dilatation of the entire main duct, isolated stenosis, and dilatation of accessory ducts; and (3) massive dilatation and stenosis of the entire duct system. Cysts were found in all stages. Results of the secretin-pancreozymin test were also grouped into four stages (0) normal findings; (1) normal bicarbonate values with decreases in one or more of the enzymes measured (amylase, trypsin, and chymotrypsin); (2) decreased bicarbonate values with normal enzyme levels or decreases in one or nore enzymes; and (3) maximum bicarbonate concentrations below the 3-σ limit with decreases in one or more enzyme. The results of these two tests agreed in 11 of the 23 patients (48%) with stage 0 findings in either the radiological or secretion test; in three of the 18 patients (17%) with stage 1 findings; and in only one of the 10 patients (10%) with stage 2 findings. However, the results of the two tests agreed in 11 of the 15 patients (73%) with stage 3 findings. Of the 19 patients with stage 1 or 2 radiological findings, 10 had normal pancreatic function, while only two patients with normal radiological findings had abnormal pancreatic function. In 15 cases the radiological findings were more abnormal than results of the pancreatic function test, but pancreatic function was more abnormal than radiological findings in only five cases. Therefore, in the early stages of chronic pancreatitis, endoscopic retrograde pancreatography is of more diagnostic value than the secretin-pancreozymin test.

2883 THE DIAGNOSIS OF PANCREATIC FUNCTION WITH THE ^{75}SELENOTHIONINE TEST. *(Ger.)* Dressler, J.; Hor, G.; Butterman, G.; Pabst, H. W. (Clin. Nucl. Med., Tech. Univ., Munich, Germany). *Munch. Med. Wochenschr.* 117(7):237-240, 1975.

After injection of ^{75}Se-methionine (0.3 μCi/kg i.v.) and pancreatic stimulation with 1 IU/kg secretin and 1 IU/kg pancreozymin, the activity of ^{75}Se-methionine and pancreatic secretion were studied in 5 samples of duodenal juice collected at 20 min intervals from 50 patients, 44 of whom had clinical signs of pancreatic disease. The concentrations and total quantities of amylase and trypsin were measured in the duodenal juice along with its volume, pH, and bicarbonate content. A significant correlation between ^{75}Se-methionine radioactivity and trypsin output was found in all fractions of duodenal juice but the first. The correlation between ^{75}Se-methionine and amylase was not as close. In these 50 patients, the results of the ^{75}Se-methionine test agreed with the clinically established diagnosis in 40 cases. False-positive and false-negative results were obtained in 2 cases each. Therefore, the ^{75}Se-methionine test can be used to study exocrine pancreatic function in place of enzymatic methods. By using pancreatic scintigraphy with the ^{75} Se-methionine test, information can be obtained about the morphology and function of the pancreas.

2884 X-RAY EXAMINATION OF THE GASTROINTESTINAL TRACT WITH A NEW BARIUM CONTRAST MEDIUM. *(Ger.)* Stallmann, K. (Lennep Hosp., Remscheid, Germany). *Leber Magen Darm* 4(4):164-166, 1974.

Barium sulfate Fertig Suspension (C. H. Boehringer & Son Co.) is a contrast medium with a low viscosity and high barium sulfate concentration which also contains dissolved carbon dioxide. For a stomach examination, 150-200 ml are usually required and for a contrast enema, 300-600 ml. This new contrast medium was used to perform x-ray examinations on 178 patients. The examinations consisted of 121 of the stomach and duodenum, 35 of the esophagus, 12 of the small intestine, and 10 of the colon. In most cases, exposures of the esophagus, stomach, and duodenum were taken in several planes with the patient's head lowered. Additional injection of a spasmolytic (40-80 mg of N-butylscopolammonium bromide) facilitates visualization of a hiatus hernia or esophageal varices. If the patient is positioned correctly, the contours of the gastric mucosa are visualized as they are by the double-contrast method. It is also possible to perform hypotonic duodenography with this contrast medium. The contrast medium reached the cecum after 1.5 hr at the most so that a complete diagnosis of the small intestine can be obtained routinely in a reasonable length of time. The carbon dioxide in the contrast medium eliminated the necessity of insufflating the colon with air to obtain double-contrast exposures.

2885 ECHOTOMOGRAPHIC AND ARTERIOGRAPHIC FINDINGS IN ACUTE HEMORRHAGIC PANCREATITIS: REPORT

OF ONE CASE. *(Fr.)* Gillet, M.; Combe, J.; Aubert, D.; Weill, F.; Ricatte, J. P.; Runser, C. (Univ. Hosp. Cent., Besancon, France). *Chirurgie* 99(10):727-733, 1973.

A 58-yr-old man with a 5 yr history of severe hypertension discontinued therapy (low-sodium diet, altizide, hydergine) and was hospitalized with a series of cerebrovascular accidents, renal failure, and increased serum amylase levels suggestive of acute pancreatitis. He spontaneously developed a huge abdominal mass and a large lumbar hematoma on the right in the absence of local injections or any abdominal trauma. By this time serum amylase activity had normalized, but serum lipase activity increased. Celiomesenteric arteriography revealed unusual vascular abnormalities which included irregular stenosis, segmental thrombosis, and leakage of the contrast medium, suggestive of a malignant lesion, probably an epithelioma or sarcoma, in the head of the pancreas. Echotomography initially revealed the presence of a pseudotumor in the head and neck of the pancreas, but a follow-up examination showed active necrosis. At surgery a hematoma the size of an orange was found in the root of the mesentery; this hemorrhagic mass involved the uncinate process of the pancreas and communicated with a larger, submesocolic mass which involved all but 3 cm of the tail of the pancreas. A subtotal, intracapsular sequestrectomy was performed with drains being placed in the stomach and gallbladder. Postoperatively, the patient's lipase levels returned to normal after 4 days, but severe renal failure persisted and an external pancreatic fistula developed. Although the fistula healed after a month, rapid increases in blood nitrogen and potassium necessitated many sessions of renal dialysis, and the patient died suddenly, 42 days after surgery, of massive gastrointestinal bleeding. In this patient, selective arteriography demonstrated the vascular origin of the pancreatitis: the intrapancreatic hematoma accounted for shunts from the superior mesenteric and gastroduodenal arteries; stenosis was caused by extrinsic compression of the Riolan's arcade; and pools of blood were probably associated with vascular erosions. Echotomography is considered superior to selective arteriography for the diagnosis of acute pancreatic necrosis since it is safer and easier to perform, can be repeated several times on consecutive days without discomfort, and is the only paraclinical examination which gives objective information about the evolution of pancreatic necrosis.

2886 ANGIOGRAPHY IN DIAGNOSIS OF SMALL BOWEL TUMORS. *(E.)* de Schepper, A.; Hubens, A.; van Vooren, W.; Verbraeken, H. (Dep. Radiol., Univ. Instelling, Antwerp, Belgium). *Radiologe* 14(9):425-430, 1974.

The findings of selective angiography of the visceral arteries in previous investigations of gastrointestinal hemorrhage have been tabulated and placed into 8 major groups: 1) arteries supplying the tumor are dilated and more rapidly filled than adjacent arteries; 2) rich vascularization with an enlarged number of arterioles, but regular in size and course, and early filling of the arteriolar network; 3) irregular, moniliform aspect of the arterioles; 4) infiltration, encasement and abrupt ending of the arteries and arterioles; 5) intensified tumor opacification in the capillary-parenchymatous phase, homogeneous contrast stain, dense but with well defined borders, sometimes with a ringlike appearence; 6) irregular pooling of contrast, along with a mottled or heterogeneous pattern of the tumor; 7) intratumoral filling defect due to necrosis, with or without central contrast extravasation; and 8) early and massive venous drainage with or without dilatation of the efferent veins. It is noted that angiographic findings often overlap. Thus, a predominance of groups 2 and 5 signs were noted in benign tumors; a predominance of symptoms 2 and 3, in malignant tumors. Groups 1 and 8 signs have been found to represent predominantly benign cases. It is concluded that, in the event conventional radiology fails, angiography may discover a tumor and provide information regarding localization and extent. To a lesser degree, it may also give an indication as to the nature of the lesion. Angiography may be used to confirm the diagnosis in cases of known or suspected tumor. In using angiography one must remember the ill-defined signs of some tumors and the lack of definite criteria to differentiate benign and malignant lesions. The angiographic information concerning localization, size, extent and sometimes nature of the small bowel tumor is, however, of extreme value in the preoperative screening of patients with gastrointestinal bleeding.

GASTROINTESTINAL DISEASES

ESOPHAGUS

2968 OESOPHAGOSCOPY, BIOPSY, AND ACID PERFUSION TEST IN DIAGNOSIS OF 'REFLUX OESOPHAGITIS'. *(E.)* Sladen, G. E.; Riddell, R. H.; Willoughby, J. M. T. (St. Bartholomew's Hosp., London, England). *Br. Med. J.* 1(5949):71-76, 1975.

Endoscopic assessment of 71 patients with possible reflux esophagitis was compared with radiological findings, esophageal biopsy studies, and acid perfusion tests. All patients had chronic continuous or intermittent esophageal symptoms, some typical and some atypical for reflux esophagitis. Typical symptoms included pain or discomfort in the retrosternal area associated with either relationship to posture, aggravation by swallowing, and relief by antacids. Atypical symptoms included retrosternal pain or discomfort unaccompanied by any of the above features, pain in the epigastrium or abdomen, regurgitation or flatulence with no discomfort, upper gastrointestinal blood loss, or isolated dysphagia. Routine radiography showed no abnormality other than sliding hiatus hernia in 46, 20 of whom showed evidence of reflux. The entire esophagus was examined by endoscopy; evidence of esophagitis was based solely on the presence of mucosal friability. Biopsy specimens from macroscopically abnormal areas in 36 patients, or from random points in the distal 10 cm were assessed without knowledge of the symptoms or endoscopic findings. Acid perfusion tests were also performed in 48 patients. Endoscopic results showed the patients with typical symptoms had a higher incidence of endoscopic abnormality than those with atypical symptoms, and had a significantly higher incidence of radiologically demonstrable reflux. True reflux esophagitis was present in 1/3 of these. The histological studies showed a greater incidence of abnormality in patients with typical symptoms, but this was not statistically significant. The acid perfusion test results were positive in most patients (14) with typical symptoms, and only five with atypical symptoms. Statistically significant correlations were also found between the acid perfusion test and endoscopic abnormality. It is concluded that the acid perfusion test is useful in the diagnosis of atypical reflux symptoms, but endoscopy and biopsy should be limited for the few patients with special problems or for clarification of a radiological lesion.

2969 THE ASSOCIATION OF CARCINOMA OF THE ESOPHAGUS WITH ACHALASIA. *(E.)* Hankins, J. R.; McLaughlin, J. S. (Univ. Maryland Sch. Med., Baltimore). *J. Thorac. Cardiovasc. Surg.* 69(3):355-360, 1975.

Two case reports are presented of esophageal carcinoma found among 156 achalasia patients over a 13 yr period. The patients were a 33-yr-old black male who presented with dysphagia complicated by hematemesis and melena, and a 60-yr-old white male who presented with dysphagia of 10-15 yr duration and a 4-5 month history of epigastric pain, nausea, regurgitation, hematemesis, and melena. Squamous cell carcinoma was found at biopsy in both cases in addition to achalasia diagnosed by esophagograms. A review of the literature indicated a carcinoma incidence in achalasia of 1-7.7% in clinically diagnosed cases, and 20-29% when found at autopsy. Analysis of 78 cases since 1970 showed achalasia symptoms are present an average of 20 yr before carcinoma is diagnosed. The average age at diagnosis was 48-52 yr. The ratio of men to women was 2.8:1 despite greater frequency of achalasia in women. Treatment was the same as for carcinoma without achalasia, including esophagogastrectomy and radiation therapy; however, prognosis was worse. Of the 2 cases presented here, the 1st developed a recurrence after surgery and the patient died shortly after a 2nd operation. The 2nd patient developed a pyloric spasm 5 months after surgery, and a possible lymph node metastasis. It is emphasized that more attention be directed to prevention and early detection of this condition.

STOMACH

3008 ALCOHOL INJURY TO GASTRIC MUCOSA IN MICE AND ITS POTENTIATION BY STRESS. *(E.)* Kawashima, K.; Glass, G. B. J. (New York Med. Coll., N.Y.). *Am. J. Dig. Dis.* 20(2):162-172, 1975.

The role of alcohol in gastric mucosal injury, with and without stress, was studied in 423 Swiss-Webster mice. All mice were fasted 6 hr prior to and 3 hr after ethanol administration. Ethanol with water was administered by esophageal intubation to 204 mice in 4 concentrations (10%, 25%, 35%, or 50% vol/vol) and in 5 doses (1, 2, 3, 4, or 5 g/kg). Each group was studied after 6, 24, and 72 hr. In 45 mice, several doses were given over 3-5 consecutive days. In the remaining 120 mice, the effect of stress (1 hr restraint in a narrow tube at 8 C) was studied in combination with the ethanol. Of these, 48 were given ethanol prior to the stress, and the other 48 after stress. In half of each group, the ethanol concentration given was 25%; in the other half, 35%; half the mice were sacrificed after 6 hr, and the other 1/2 after 24 hr. For concentrations of 25% and greater, increasing dosages of ethanol caused a rapid increase in gastric erosions. At the 5 g/kg dose, erosion incidence reached 100% with the 35% concentration. At any particular dosage, increasing concentration caused increased erosion. At the 4 and 5 g/kg doses, erosion incidence was 0 at the 10% concentration, 67% at 25%, 76% and 100% at 35%, and 100% at 50% ethanol. In the mice given ethanol for 3-5 days, the 3 g/kg dose over 5 days produced a 67% incidence of erosion for both concentrations after 6 hr, 33% after 24 hr, and 0% after 72 hr. Stress alone caused hyperemia in 25% of the mice, while ethanol alone caused 30% hyperemia in 25% concentration at 3 g/kg. Combination of the alcohol and the stress was less than additive. When 35% ethanol at 3 g/kg was given before stress was applied, effects were greater than additive (ethanol, 37% incidence; stress, 35%; both, 83%).

There was a 27% incidence of gastric erosion with 35% ethanol at 3 g/kg; stress gave a 4% incidence; and both, a 50% incidence when the stress was first, and 71% when the ethanol was first. It is concluded that incidence of gastric erosion is significantly potentiated by stress, especially when stress is applied after ethanol.

3009 THYROGASTRIC AUTOIMMUNE DISEASE. STUDIES ON THE CELL-MEDIATED IMMUNE SYSTEM AND HISTOCOMPATIBILITY ANTIGENS.

(E.) Whittingham, S.; Youngchaiyud, U.; Mackay, I. R.; Buckley, J. D.; Morris, P. J. (Walter and Eliza Hall Inst. Med. Res., Victoria, Australia). *Clin. Exp. Immunol.* 19(2): 289-299, 1975.

The role of cell (T-cell) mediated immunity was investigated in thyrogastric autoimmune disease. Twelve patients with autoimmune thyroiditis, and 27 with autoimmune gastritis were tested for specific cell-mediated responses to thyroid antigen by the leukocyte inhibition migration technique. In addition, general cell-mediated immunity to extrinsic antigens was tested for by cutaneous 1-chloro-2,4-dinitrobenzene response, response to 5 ubiquitous antigens, and lymphocyte blastogenic response to phytohemagglutinin. Finally, human leukocyte antigen (HL-A) phenotypes were determined. For each test, 26 normal volunteers served as controls. Leukocyte migration indices for chambers containing 100 μg of human thyroglobulin for the thyroiditis patients and controls were 0.79 and 1.1, resp. The indices for the chambers containing 200 μg gastric parietal cell microsomes were 0.78 and 1.1 for gastritis patients and controls, resp. When gastritis patient leukocytes were tested in human thyroglobulin and those from thyroiditis tested in gastric parietal cell microsomes results were ambiguous, leukocytes of some patients showing increased migration, and those of others decreased migration. The mean values (0.94 for thyroiditis patients tested with gastric parietal cell microsomes and 0.73 for gastritis patients tested with human thyroglobulin) were not significantly different from the control values (1.1) but the variability within the groups was highly significant in comparison with controls. Cutaneous response tests showed no significant results. HL-A typing showed a significant increase in frequency of HL-A3 and HL-A7 in the gastritis, but not the thyroiditis patients. However, this significance disappeared after a correction factor for the number of comparisons was applied. It is concluded that leukocyte inhibitory factor release is an index of specific cell-mediated immunity in thyrogastric autoimmune disease.

3010 STUDIES ON THE MECHANISM OF HYPOPROTEINEMIA IN GASTRIC CANCER. I. ALBUMIN LEAKAGE INTO THE STOMACH IN GASTRIC CANCER PATIENTS.

(E.) Yamaoka, K.; Noguchi, S.; Higashi, H.; Jinnai, D. (Osaka Univ. Med. Sch., Japan). *Jpn. J. Clin. Oncol.* 4(2):97-104, 1974.

The leakage of serum albumin into the stomach in cases of gastric carcinoma was determined in 30 patients; 8 patients without carcinoma served as controls. ^{131}I-Human serum albumin (100 μCi) was injected i.v. after 3 days administration of potassium iodide as a thyroid block. On the following day the gastric contents were aspirated, the lumen rinsed with saline, and the gastric juice was continually neutralized with phosphate buffer and collected for 1 hr. After centrifugation the sediment was counted by scintillation counter. Leakage index was expressed as A/B x 100 where A represents total count/min sediment collected in 1 hr, and B represents count/min of 1 cc serum. In 16 cases values were less than 50, in 8 cases 50-100, in 3 cases 100-200, and in 3 cases over 200; the total average was 102.42. In contrast, control values were always under 100 and averaged 32.44. To determine whether gastric cancer producing mucus was related to leakage, sections of surgical specimens from the patients were stained by the PAS method. No correlation was found. There was also no correlation between leakage and sex, age, gastric acidity, Borrmann's type, histological type or size of crater. However, patients with the highest leakage rates had marked lymphatic cell invasion by carcinoma cells. It is concluded that gastric cancer hypoproteinemia may stem from serum protein leakage into the stomach, which in turn may be due to stasis of the lymphatic fluid.

3011 THE INFLUENCE OF CARBENOXOLONE ON STEROID-INDUCED ULCER AND MUCUS SECRETION IN THE RAT.

(E.) Berg, M.; Geisel, A.; Necheles, H. (Michael Reese Hosp., Chicago, Ill.). *Am. J. Dig. Dis.* 20(2):134-137, 1975.

The protective effects of carbenoxolone sodium on prednisolone-induced ulceration were studied in 7 groups of 13 Holtzman rats each. The rats were fasted for 4 days and killed on the 5th with chloroform. Four groups were given prednisolone (3.5 or 5.0 mg s.c.) each dose with or without carbenoxolone (50 mg in 20 ml water, p.o.); 1 group carbenoxolone only; and 2 were control groups (1 fasted and 1 unfasted). Ulceration was observed in the stomachs, and mucus content was determined by determining dry weight before and after immersion in acetylcysteine. In all rats given drugs, ulceration of the squamous epithelium was found in only 1 of 50. There were no significant differences in size or number of ulcers of the glandular stomach in rats treated by both drugs or by prednisolone alone. The amount of mucus found in fasted control rats was significantly less than that of the treated groups and the fed controls, indicating that either drug or both prevents lowering of mucus in fasted rats. Histologic examination showed no differences between groups treated by prednisolone only, or by both drugs. It is concluded that prednisolone, carbenoxolone, or both are associated with prevention of ulceration, especially of the squamous epithelium, by maintaining normal amounts of mucus in fasted rats.

3012 FORMALDEHYDE-OZONE-INDUCED FLUORESCENCE IN GASTRIN-PRODUCING TUMORS.

(E.) Larsson,

L. I.; Sundler, F.; Grimelius, L.; Hakanson, R.; Buffa, R.; Solcia, E. (Dep. Histol., Univ. Lund, Sweden). *Virchows Arch.* [*Pathol. Anat.*] 365(3):179-184, 1975.

Gastrin and glucagon-producing tumors were examined for formaldehyde-ozone-induced fluorescence in 8 patients. Tumor material was obtained at surgery or autopsy and subjected to formaldehyde and ozone, or indirect immunofluorescence for gastrin, insulin, glucagon, or ACTH. In 4 patients with Zollinger-Ellison syndrome, 3 had tumors in the pancreas, and 1 in the duodenal submucosa. Formaldehyde-ozone-induced fluorescence was found in the peripheral tumor cells in each case, and gastrin immunofluorescence was found in the same areas. There was little or no glucagon, insulin or ACTH immunofluorescence. Of 2 cases of insulin-secreting tumors, 1 showed moderate insulin immunofluorescence, and no gastrin or other immunofluorescence, or formaldehyde-ozone fluorescence. The other showed intense immunofluorescence of the glucagon cells, less of the insulin cells, and still less of the gastrin cells. Formaldehyde-ozone fluorescence could not be determined. A liver metastasis of this tumor showed much gastrin, moderate glucagon, and no insulin immunofluorescence. A small amount of formaldehyde-ozone fluorescence was also detected. One case of glucagon-secreting tumor showed only intense glucagon immunofluorescence. One case of gastric carcinoma showed only intense gastrin immunofluorescence, and a strong formaldehyde-ozone-induced fluorescence. It is concluded that the association between gastrin immunoreactivity and formaldehyde-ozone-induced fluorescence is a feature of gastrin-producing tumor cells.

3013 POSTOPERATIVE REFLUX GASTRITIS. *(E.)* van Heerden, J. A.; Phillips, S. F.; Adson, M. A.; McIlrath, D. C. (Mayo Clin., Rochester, Minn.). *Am. J. Surg.* 129(1):82-88, 1975.

Postoperative reflux gastritis was studied in 49 patients (28 males, 21 females, mean age 49.9 yr) who had undergone gastric or duodenal surgery 0-42 yr (average 6.1 yr) prior to the study. The chief clinical features of the reflux alkaline gastritis were epigastric pain, bilious vomiting, anemia (hypochromic, microcytic, iron-deficiency type), and the dumping syndrome. Gastroscopy was the most valuable diagnostic procedure with adherent mucus, edema, mucosal friability, and erosions (most severe on the gastric aspect of the stoma) being the most characteristic features. Gastric biopsy supported the macroscopic diagnosis. The Roux-en-Y biliary diversion was performed in 31 of the patients and a jejunal interposition was performed in 12 patients, but the best clinical results were seen in the Roux-en-Y diversion group. Medical treatment for reflux gastritis has not been adequately evaluated.

3014 THE RELATIONSHIP BETWEEN BILE AND HYDROCHLORIC ACID IN THE PATHOGENESIS OF ACUTE GASTRIC EROSIONS. *(E.)* Himal, H. S.; Boutros, M.; Weiser, M. (Dep. Exp. Surg., McGill Univ., Montreal, Canada). *Am. J. Gastroenterol.* 62(5):405-409, 1974.

The relationship between bile and hydrochloric acid in the pathogenesis of acute gastric erosions was studied in 15 mongrel dogs using explants of antrum which were placed within lucite chambers. Instillation of a control solution (120 mEq/liter HCl and 40 mEq/liter NaCl) into the antral chamber for four consecutive 30-min periods led to a net H^+ loss and a net Na^+, Cl^- and K^+ gain, but there was no measurable volume gain. Fresh canine gallbladder bile (10 ml) in contact with antral mucosa did not lead to gross or microscopic erosions, but instillation of the acid/saline control solution in the postbile period led to increased net H^+ Na^+ flux, net K^+ gain and net Cl^- loss, and acute erosions which appeared within 5 min of the control solution instillation. These erosions increased in size and number throughout the four test periods. There was minimal diffusion of H^+ into the antral mucosa, gallbladder bile alone did not cause acute antral mucosa erosions, but bile in association with hydrochloric acid did cause acute erosions when in contact with the antral mucosa. The underlying mechanism may be related to alterations in lysosomal activity.

3015 ATROPHIC GASTRITIS IN GASTRECTOMY SPECIMENS. *(E.)* Skinner, J. M.; Heenan, P. J.; Whitehead, R. (Radcliffe Infirm., Oxford, England). *Br. J. Surg.* 62(1):23-25, 1975.

Gastrectomy specimens from carcinoma and gastric ulcer patients were studied with regard to type and distribution of chronic gastritis, the presence of intestinal metaplasia, the site of the lesion, and any previous surgery. Blocks of tissue were taken from various areas of the stomach and stained by hemotoxylin and eosin, PAS, Foot's reticulin, and a modified Maxwell's method. Atrophic gastritis and intestinal metaplasia occurred almost entirely in the pyloric region or in the adjacent lesser or greater curves. Superficial gastritis was also seen in the pyloric region in about half the pyloric ulcer cases, while body ulcers were seen in all areas. This distribution was similar to that seen in the carcinoma cases, and in cases of gastrectomy following previous gastrojejunostomy for duodenal ulcer. There was a close association of atrophic gastritis and intestinal metaplasia with the development of cancer, and a high cancer rate after stomach operations for benign conditions. The similarity of distribution of atrophic gastritis and intestinal metaplasia in the stomach with body ulcer to that in cancer and after gastrojejunostomy suggested a higher cancer risk in body ulcer cases.

3016 THE ROLE OF STARCHES IN THE ETIOLOGY OF GASTRIC CANCER. *(E.)* Modan, B.; Lubin, F.; Barell, V.; Greenberg, R.; Modan, M.; Graham, S. (Chaim Sheba Med. Cent., Tel Hashomer, Israel). *Cancer* 34(6):2087-2092, 1974.

The role of starches in the etiology of gastric cancer was studied in gastric cancer patients, and several matched control groups (colorectal cancer patients; surgical cases with neither malignancy nor gastrointestinal disorders; and neighborhood controls).

The control groups were matched to the gastric cancer cases according to age, sex, ethnic origin, and length of residence in Israel. Comparison of the gastric cancer cases and the controls pertained to individual food items and groups of foods combined on the basis of common nutritional components, and paired t-tests were used to evaluate results. The gastric cancer patients ate on the average 26 items more frequently, 16 items with equal frequency and eight items less frequently than the colon cancer cases. For every food item eaten less frequently, three were eaten more frequently by the gastric cancer patients. There was a higher consumption frequency of starches among the gastric cancer patients, and this was not related to a socioeconomic differential. It was suggested that long-term consumption of starchy foods may affect the mechanics of gastric acid secretion and thus render the gastric mucosa more susceptible to exogenous carcinogens.

3017 MUCOSAL AND HEPATIC METABOLISM DURING THE SPONTANEOUS DISAPPEARANCE OF SALICYLATE-INDUCED GASTRIC EROSIONS.

(E.) Hietanen, E. (Dep. Physiol., Univ. Turku, Finland). *Am. J. Dig. Dis.* 20(1):31-41, 1975.

The appearance and healing of salicylate-induced gastric erosions, and the mucosal and hepatic detoxification activity of salicylate was studied in 98 adult Wistar rats (84 males and 14 females). Salicylic acid was administered intragastrically (1-2 mM/kg body weight) once a day for 1-14 days, and the rats were killed 12 hr after the last dose. A single dose of salicylic acid (1-2 mM/kg body weight) caused erosions and bleeding in the gastric mucosa of all rats. After three daily doses, only slight gastric hemorrhage was observed in one of five rats at the 1 mM/kg dose, but at the dosage level of 2 mM/kg bleeding was present in two of five rats. Hepatic protein content decreased slightly after treatment, and in 2 weeks the decline was significant. The duodenal decrease was nearly significant after one mM/kg dose; after three doses there was a transient increase in protein content, whereas a significant decrease after three doses of 2 mM/kg was found. Gastric protein content showed a significant decrease after a single dose, but returned to control levels within 2 weeks. Gastric and duodenal UDP glucuronyltransferase activity decreased after a single dose of salicylic acid, but when the treatment was continued the enzyme activity increased above control level and in 2 weeks had returned to control level. Although the salicylates inhibited gastroduodenal glucuronidation *in vitro*, there was no substrate effect present when the rats were killed. Duodenal 3,4-benzpyrene hydroxylase activity was not affected by salicylic acid, and the gastric activity of this enzyme could not be measured by the methods used. Hepatic detoxification capacity was stable, however a slight depression of 3,4-benzpyrene hydroxylase activity did occur within 2 weeks. The results suggest that mucosal detoxification capacity may have a role in the pathogenesis of drug-induced gastric erosion. Gastric mucosa adapted to repeated salicylic acid administration, having reduced susceptibility to drug-induced erosions.

3018 GASTRIC MUCOSAL ISCHEMIA IN EXPERIMENTAL STRESS ULCER.

(E.) Sales, J.; Norton, L.; Nolan, P.; Rankin, J.; Eiseman, B. (Denver Gen. Hosp., Colo.). *J. Surg. Res.* 18(1):65-74, 1975.

Blood flow patterns were quantitatively studied in the stomachs of 25 6-12-week-old piglets using isotopically labeled microspheres to investigate the pathogenesis of gastric ulceration following major blood loss. The left carotid artery and right external jugular vein were catheterized with 15-gauge polyethylene tubing. A similar catheter passed through the right femoral artery into the abdominal aorta. From 600,000 to 1,000,000 carbonized plastic microspheres labeled with ^{141}Cerium with a specific activity of 10 mCi/g were injected over 3 sec into the left ventricle. All 4 nonhemorrhaged animals survived anesthesia. Fifteen of 21 piglets survived hemorrhagic shock. Five of six piglets in which hemorrhagic shock was induced by bleeding 40% of the estimated blood volume survived hemorrhage. No gastric ulceration occurred in the survivors, which were sacrificed immediately after hemorrhage. Total gastric blood flow ranged from 18 to 81 ml/min. Mean values of total gastric blood flow showed a 70% decrease and these changes were reflected in the fall of average flow/g of the fundus-body (mean 59%) and antrum (mean 70%). Five of nine animals survived 90 min of hemorrhagic shock. Three survivors developed ulcers in the body of the stomach and two showed petechial lesions in the fundus. Total gastric blood flow was 9.5-60 ml/min. Blood flow to the fundus body decreased a mean 76% and to the antrum a mean 77%. After 90 min of shock, gastric mucosal flow became grossly uneven: 48% of fundus-body squares (1 cm each) had normal, 19% had high, and 33% had low flow compared to prehemorrhage values. Squares with low flow were distributed in an uneven fashion in the fundus-body and ulceration occurred principally in these squares. Five of six piglets survived 90 min of shock and retransfusion. Three survivors developed ulcers in the gastric corpus within 2 hr of hemorrhage. Total gastric blood flow ranged from 5.3 to 14 ml/min. The distribution of gastric blood flow was uneven after 90 min of shock. After retransfusion flow became even in two piglets but remained grossly uneven in three. Ulceration occurred in areas of low relative flow. These experiments show that decrease in blood flow in the swine stress ulcer model is not evenly distributed and that parts of the fundus-body and antrum are disproportionately ischemic. The findings suggest that uneven flow is not due to ulcer formation but that ulceration is etiologically related to ischemia.

3019 MORPHOLOGY OF GASTROINTESTINAL EFFECTS OF ASPIRIN.

(E.) Hahn, K. J.; Krischkofski, D.; Weber, E.; Morgenstern, E. (Dep. Med., Univ. Heidelberg, Germany). *Clin. Pharmacol. Ther.* 17(3):330-338, 1975.

The effect of aspirin on the ultrastructure of gastric mucosa and intestinal mucosal cells was investigated in the guinea pig and in man. Of 6 patients undergoing Billroth II operations, 3 were given 1 g aspirin/day 3-5 days prior to surgery, the remaining

3 serving as controls. For comparison, 5 guinea pigs were given 1 ml 45 mM aspirin solution in 2.5% alcohol 3 times/day for 4 days. Five control animals received only the alcohol. In 2 of 4 groups (2 animals each) gastric secretion was stimulated by 2 mg/kg betazole. In the other 2 groups, secretion was inhibited by 1 U/kg secretin. In all 4 groups, 1 ml of a 45 mM aspirin solution in 0.07 N NaOH, or 1 ml of pure 0.07 N NaOH was administered 15, 60, and 120 min after injection. Gastric and intestinal mucosa of control patients appeared normal under both light and electron microscopy. In patients given aspirin, surface mucous cells showed signs of cytolysis and desquamation. Many gastric parietal cells showed up to a 1 μm increase in lysosomal diameter and contained homogeneous and lamellar material, vesicular structures, and lipid droplets. No changes were found in the intestinal mucosa. In the guinea pigs, 4 day administration caused gastric mucosal superficial cells to exhibit the cytolytic signs of swollen nuclei and lighter cytoplasm. Similar effects, plus many small erosions, resulted from short-term aspirin treatment and betazole. The electron microscope showed surface mucosal cells exhibiting such cytolytic signs as pyknosis of the nucleus, clumping of the chromatin, and lysis of the cytoplasm and organelles. Lysosomes were not observed in mucosal cells, even after lengthy aspirin exposure. In the intestinal mucosa, electron microscopy showed fewer secondary lysosomes and multivesicular bodies than the gastric mucosa of human controls and control animals. Secondary lysosomes resembled those of gastric parietal cells in aspirin-treated patients. It is concluded that cytoplasmic damage by aspirin may induce hydrolase transport by multivesicular bodies and formation of autophagolysosomes.

3020 DISTRIBUTION OF GASTRIN IN HUMAN DIGESTIVE ORGANS DEMONSTRATED BY DIRECT IMMUNOFLUORESCENCE.

(E.) Tobe, T.; Henmi, D.; Fukuchi, K.; Chen, S. T.; Tachibana, S. (Kyoto Univ. Med. Sch., Japan). *Arch. Histol. Jpn.* 37(1):59-72, 1974.

Immunofluorescence studies were performed on different portions of the human digestive tract to determine gastrin distribution. Antral stomach tissue from 15 gastric carcinoma patients, 15 peptic ulcer, and 4 benign adenoma patients given gastrectomies; and normal tissues from stomach, duodenum, jejunum, ileum, colon, rectum, pancreas, parotid gland and submandibular gland were examined. To determine glycine gastrin release, an antral section was immersed in 0.5 M glycine for 30 min and examined by immunofluorescence. Gastrin-containing cells were found in quantity in the antrum of the stomach, but none in the cardia. They were dispersed in the cryptal epithelium and in the middle zone of mucosal thickness. Most heavy concentrations were 2-4 cm proximal to the pylorus, becoming sparser in the pylorus. In the duodenum, the number of gastrin containing cells was lower than in the antrum and became increasingly lower distal to the pylorus. None were found in the jejunum, ileum, colon, rectum, esophagus, pancreas, parotid or submandibular glands. Gastrin fluorescence in antral tissue showed a slight decrease after immersion in glycine solution. In contrast, complete gastrin release resulted after freezing in an isopentane flask at -30 to -70 C. It is concluded that the gastrin-containing cells are only found in the antrum in great numbers, and to a lesser extent in the duodenum.

3021 CYTOHISTOCHEMICAL STUDIES OF THE EXOCRINE PANCREAS AFTER SUBTOTAL RESECTION OF THE STOMACH.

(Rus.) Zufarov, K. A.; Tashkhodzhaiev, P. I.; Alizhanov, G. A.; Gontmakher, V. M. (Tashkent Med. Inst., USSR). *Arkh. Anat. Gistol. Embriol.* 67 (9):41-47, 1974.

Changes in the exocrine pancreas were studied in mongrel dogs sacrificed 5-360 days after subtotal stomach resection. In the early postoperative period (5-20 days), inflammatory, hemodynamic and slight destructive changes were observed. Intrapancreatic vessels and capillaries were dilated and filled with blood, and the intralobular connective tissue was swollen and infiltrated by lymphohistiocytic elements. The size of the nuclei in the acinar cells decreased by 6.5% compared with the controls. One to three months after surgery, the vasomotor and inflammatory process became subdued, while destructive processes developed. In addition to atrophic changes in the pancreas and the inhibited activity of the acinar cells, there was evidence of impaired secretion which was demonstrated by the presence of immature secretory granules in the acinar cells. It is suggested that subtotal resection entailed more profound degenerative changes in the pancreatic parenchyma than vagotomy. The degenerative and atrophic changes may be related to the impaired neurohumoral regulation of the pancreatic function. One year after surgery, a steady improvement in the histostructure of the exocrine pancreas was observed, characterized by the presence of enlarged acini, hypertrophy of acinar cells, elevated content of nucleic acids in the cells and an increase in the average size of the nuclei in the acinar cells. A partial regeneration of the pancreas as a long-term result of stomach resection may suggest a possible enhancement of the hormone influx from the jejunum. However, due to a slow rearrangement of this part of the stomach, the atrophy of the pancreas and the inhibition of its excretory function is the early postoperative consequence of the resection.

STOMACH

Peptic Ulcers

3054 INHIBITION OF GASTRIC SECRETION IN MAN BY ORAL ADMINISTRATION OF CALCITONIN. *(E.)* Ziegler, R.; Minne, H.; Hotz, J.; Goebell, H. (Cent. Intern. Med. Pediatr., Univ. Ulm, Germany). *Digestion* 11(1/2):157-160, 1974.

The sensitivity of the human stomach to oral calcitonin was studied. Gastric juice was collected from normal subjects at 30-min intervals, following calcitonin administration by stomach tube, and again after the administration of pentagastrin (0.8 μg/kg/hr i.v.) followed by calcitonin. Determinations were made for gastric acidity, pepsin content, and serum calcium. Synthetic human calcitonin induced a distinct inhibition of basal as well a pentagastrin-stimulated gastric secretion and pepsin output which was primarily a volume reduction. Acid and pepsin concentrations only slightly diminished. The inhibition was induced by 50-100 MRC U of human calcitonin or 1,400 MRC U of salmon calcitonin. Serum calcium levels did not change during the tests. Because of its therapeutic implications, an investigative trial of oral calcitonin administration in peptic ulcer disease is suggested.

3055 INTESTINAL CALCIUM ABSORPTION AFTER PARTIAL GASTRECTOMY. *(E.)* Nicolaou, A.; Alevizaki, C. C.; Ikkos, D. G.; Philokyprou, G. (Hippokrateion Hosp., Athens Univ. Med. Sch., Greece). *Am. J. Gastroenterol.* 62(6):516-525, 1974.

The intestinal absorption of calcium after gastrectomy was determined by a double radiocalcium tracer technique in 39 patients who underwent Billroth I or II operations for peptic ulcer between 4 months and 30 yr prior to the study. Each was given an oral dose of 140 mg labeled $CaCl_2$ in water along with a standardized light breakfast containing 80 mg calcium.

In all but 7 patients, fasting serum calcium, inorganic phosphate, and alkaline phosphatase, were measured and a d-xylose test was performed. The coefficient of true intestinal calcium absorption (a) varied between 7.7% and 5.0%. The mean $\log_{10}$ a-values of the gastrectomized patients (1.421) were significantly lower than those of the controls (1.536). The a-values were influenced by the interval between the operation and the study. Thus the mean $\log_{10}$ a-value of the early post-gastrectomy group (0-5 yr) was significantly lower (1.355) than that of the controls (1.530) or of the late post-gastrectomy group (6-30 yr, 1.478). By plotting a-values against patients' ages, age was ruled out as a factor in the difference between values of normal and gastrectomized patients. No significant correlations were found between a-values and inorganic phosphate or alkaline phosphatase values, or d-xylose absorption test results. Serum calcium showed a positive linear correlation for the 6-30 yr postgastrectomy group. Results confirm previous findings that reduced intestinal calcium absorption occurs in post-gastrectomy patients.

3056 SALIVARY SECRETION IN EVOLUTIVE AND QUIESCENT DUODENAL ULCER. *(E.)* Andre, F.; Descos, F.; Andre, C.; Lambert, R. (INSERM, Edouard-Herriot Hosp., Lyon, France). *Digestion* 11(1/2):98-104, 1974.

A comparison of salivary and pharyngeal secretions in healthy subjects and in patients with a duodenal ulcer was made to determine the significance of the outputs of organic and inorganic components of the saliva. Samples of the saliva stimulated by a gastric tube were collected from 9 healthy male volunteers (mean age 31 yr) and 9 male patients suffering from duodenal ulcer (mean age 33 yr). The volume was measured, and the constituents determined (fucose, total hexosamines, sialic acid, sulfate, proteins, free calcium and total calcium). In patients with an evolutive duodenal ulcer, the salivary outputs of fucose, hexosamines and sulfate were lower than in controls, and most of the calcium was found in the bound form. In patients with healed duodenal ulcer, the salivary outputs were greater than in controls, and the distribution pattern of calcium was the same as that in healthy subjects. It is suggested that the decreased glycoprotein secretion observed in the saliva of patients with an evolutive duodenal ulcer is a transient abnormality concomitant to the duodenal crater rather than a determining factor, and that the increased secretion measured in patients with healed ulcer could be related to enlargement of their salivary glands.

3057 PLASMA-GASTRIN AND ACID SECRETION IN PATIENTS WITH PEPTIC ULCERATION. *(E.)* Wesdorp, R. I. C.; Fischer, J. E. (Massachusetts Gen. Hosp., Boston). *Lancet* 2(7885):857-860, 1974.

In 132 patients with peptic ulceration, 101 with a duodenal ulcer and 31 with a gastric ulcer, the relationship between basal plasma-gastrin levels, basal intragastric pH, and basal and stimulated gastric-acid secretion was examined. The mean basal plasma-gastrin level for the 101 duodenal ulcer patients was 61 pg/ml, and was 93 pg/ml for gastric ulcer patients, compared to 54 pg/ml in 30 healthy controls. The mean basal intragastric pH was significantly lower in the duodenal ulcer patients (1.8) than in gastric ulcer patients (2.6). Throughout the study, basal plasma-gastrin appeared to be related to basal intragastric pH, but when the patients were grouped according to their pH, and plasma-gastrin values were compared, no significant differences were found between the groups. When they were grouped according to their basal gastric-acid secretion and their plasma-gastrin values compared, there was no significant difference between the groups and no inverse relationship. The results suggest that the duodenum may make a major contribution to basal circulating gastrin or that there may be some autonomy of gastrin release in duodenal-ulcer patients, since there was no decrease in plasma-gastrin levels as basal gastric-acid secretion increased. It also appears that basal acid secretion is independent of plasma-gastrin.

3058 DUODENAL ULCERATION IN ALLERGIC CHILDREN. *(E.)* Rebhun, J. (Dep. Med., Loma Linda Univ., Calif.). *Ann. Allergy* 34(3):145-149, 1975.

A diverse group of children with duodenal ulcerations and allergies was studied to determine whether the children's ulcer symptoms were functional or morphological. Children (43, 5-18 yr) suffering from a variety of allergies showed manifestations of ulceration classified as moderate in 30 cases, severe in 10, and intractable in three. X-ray findings showed 25 with definite ulceration, 12 with no definite crater but with spasm of the antrum and/or pylorus, and six with suspicious ulceration and spasm. Most of the ulcers responded to conventional ulcer therapy and were not present when x-rayed again 4-5 weeks later. The functional stomach ache often observed in allergic children might be explained by the organic changes. It is suggested that the chronic release of histamine-like substances, stress connected with a chronic illness, food sensitivities, and ulcerogenic drugs might be the factors affecting the allergic individuals so that the incidence of duodenal ulceration is greater among them than in the nonallergic children.

3059 THE ROLE OF SECRETIN IN THE INHIBITION OF GASTRIC SECRETION BY INTRADUODENAL ACID. *(E.)* Ward, A. S.; Bloom, S. R. (Sheffield R. Infirm., London, England). *Gut* 15(11):889-897, 1974.

The effect of intraduodenal acid and exogenous secretin on pentagastrin-stimulated gastric secretion was studied in 12 normal subjects and 23 patients with chronic duodenal ulceration. Pentagastrin (6 μg/kg/hr i.v.) was administered to normal subjects and duodenal ulcer patients followed by 40 ml of 0.1 N HCl labeled with 2% polyethylene glycol infused into the distal duodenum. Gastric samples were collected at 10-min intervals, and plasma secretin levels were monitored using radioimmunoassay. Significant inhibition of gastric secretion occurred in the normal subjects (4.77-2.88 mEq/10 min) and duodenal ulcer patients (7.41-5.53 mEq/10 min). A significant rise in plasma secretin was observed in both groups (normals, 19.1-58.3 pg/ml; ulcer patients, 13.2-42.9 pg/ml), but there was a complete lack of correlation between the magnitude of the secretin response and the degree of gastric inhibition. Ten subjects received intraduodenal acid and a subsequent infusion of exogenous secretin (0.125-0.25 U/kg over 6 min). Gastric inhibition occurred after the acid instillation but not after the secretin infusion; plasma secretin levels rose to values greater than those produced by intraduodenal acid. The results provide evidence that secretin is not significantly involved in the inhibitory response to intraduodenal acid in man.

3060 STUDIES ON CHANGES IN LIPID PROFILES OF THE RAT GASTRIC MUCOSA WITH STRESS ULCERS.

(E.) Slomiany, A.; Slomiany, B. L.; Horowitz, M. I. (New York Med. Coll., N.Y.). *Clin. Chim. Acta* 59(2): 215-226, 1975.

Changes in gastric mucosal neutral lipids, phospholipids, and glycolipids were studied in normal rats and in restrained rats which developed stress ulcers. Sprague-Dawley rats were fasted and immobilized in wire screens for 24 hr. The animals were killed, the stomachs removed and examined for ulceration, and the gastric mucosa scraped and prepared for analyses. Organic solvent extraction, silicic acid column, and thin-layer chromatography were employed to separate, and gas-liquid chromatography and spectrophotometry to quantitize the individual lipid components. Chemical analysis revealed profound alterations in the mucosal lipid profiles of rats with gastric mucosal erosions. Cholesterol esters were markedly elevated, 12.11 μM/100 mg lipids compared to 2.38 μM/100 mg lipids in controls. Cholesterol, free fatty acids, and phosphatidylethanolamine were lower in the extracts of ulcerated tissue, but the titer of lysophospholipids was about 8 times higher than in the controls. Lipid phosphorus was also elevated in stressed rats. The amount of neutral glycolipids was similar for both groups, but tetra- and oligohexoside ceramides, which were present in the gastric mucosa of the control rats, were virtually absent from the ulcerated mucosa. In contrast to the alterations in lipid profile, the total lipid weight/tissue preparation was very similar for the ulcerated and normal control groups. It is suggested that a shedding of membrane fragments could lead to a selective loss of certain lipid constituents, or that surface-active lipids may be causal agents in altering lipid composition of the mucosa.

3061 A COMMON DENOMINATOR IN THE PATHOGENESIS OF PEPTIC ULCERATION.

(E.) Fiddian-Green, R. G. (Univ. Cape Town Med. Sch., South Africa). *S. Afr. J. Surg.* 12(3):163-172, 1974.

The gastric secretory responses to histamine were analyzed in 59 controls, 70 patients with duodenal ulcers and 32 patients with gastric ulcers to reassess data concerning ulcer pathogenesis. Gastric juice was collected by a nasogastric tube following i.v. infusion of histamine (0.04 mg/kg/hr), then measured for volume, titratable acidity, and concentration of Na^+, K^+, and Cl^-. Phenol red was used as an inert marker of pyloric reflux; sodium was used as a means of calculating volume of pyloric reflux within aspirated gastric juice. A statistically significant hypersecretion of gastric juice and an excessive degree of pyloric reflux were found in only a minority of patients. In the controls there was a significant positive correlation between the magnitude of the pyloric losses of acid and the bicarbonate concentration in the duodenum juice. There was no such correlation in either the patients with duodenal ulcers or the patients with gastric ulcers. The abnormal response to duodenal acidification in ulcer patients is the basis for a working hypothesis to account for the abnormalities in gastric secretory responses observed in patients with peptic ulcers.

3062 ACID HYPERSECRETION AND DUODENAL ULCERS PRODUCED BY CYSTEAMINE IN RATS.

(E.) Groves, W. G.; Schlosser, J. H.; Mead, F. D. (Dep. Pharmacol., Smith Kline French Lab., Philadelphia, Pa.). *Res. Commun. Chem. Pathol. Pharmacol.* 9(3): 523-534, 1974.

The role of acid hypersecretion in the pathogenesis of cysteamine duodenal ulcer was studied in rats. Cysteamine, in various doses, was administered p.o. to 1-hr pylorus-ligated Charles River rats. The animals were autopsied 24 hr after the initial dose to determine the number and appearance of gastric and duodenal ulcers. A dose-related ulcerogenic effect was seen, and at 1 g/kg dose 1/2 the rats died. Cysteamine greatly increased acid secretion: 0.25 g/kg resulted in acid output 78% above controls; 1 g/kg resulted in acid output 277% above controls; the peak occurred 6-7 hr post-drug (0.5 g/kg) and was 662% above controls. Ulcers tended to occur selectively in the duodenum at low dose (88% incidence in duodenum, 24% incidence in stomach) but found equally often in stomach and duodenum at high dose. Their formation was associated with prolonged hypersecretion of highly acidic gastric juice thought to be the result of endogenous histamine release by cysteamine and/or its metabolite, cystamine.

3063 REPRODUCIBILITY OF PLASMA GASTRIN CONCENTRATION AND GASTRIC PEPSIN OUTPUT AFTER INSULIN-INDUCED HYPOGLYCAEMIA.

(E.) Elder, J. B.; Walker, D. I.; Ganguli, P. C.; Gillespie, I. E. (R. Infirm., Manchester, England). *Scand. J. Gastroenterol.* 9(8):731-734, 1974.

Plasma gastrin concentration and gastric pepsin output following insulin-induced hypoglycemia were studied to establish the reproducibility of the responses. The tests were performed twice on 13 peptic ulcer patients. Gastric secretion was collected by nasogastric tube at 15-min intervals for 3 hr, and again after i.v. insulin (0.2 U/kg). Blood samples were taken simultaneously. Peptic activity was assayed using radioiodinated human serum albumin as a tracer, plasma gastrin concentration by radioimmunoassay. Basal, peak, and 2-hr output of pepsin after insulin hypoglycemia values were reproducible (2-hr output most consistent). No significant difference was found in the data from the two tests. Values for serum gastrin concentration after insulin were widely scattered, but the overall pattern of the two tests was similar. Only the 2-hr gastrin output was found to be reproducible. The results cast doubt on the suitability of insulin as a stimulus for gastrin secretion.

3064 ACID SECRETION AND SERUM GASTRIN FOLLOWING INSULIN AND 2-DEOXY-D-GLUCOSE IN DUODENAL ULCER PATIENTS. *(E.)* Emas, S.; Svensson, S. O.; Dorner, M.; Kaess, H. (Dep. Surg. Clin. Physiol., Univ. Lund, Sweden). *Scand. J. Gastroenterol.* 9(7): 629-637, 1974.

The relationship of gastric acid response and serum gastrin concentration following insulin and 2-deoxy-D-glucose was studied in 30 patients with duodenal ulcer. Following administration of insulin (0.2 U/kg i.v.) or 2-deoxy-D-glucose (50 mg/kg i.v.) gastric secretion was collected at 15-min intervals. Serum gastrin concentration was determined by radioimmunoassay. The basal gastrin level varied but was unrelated to basal acid output or pH of the secretion. 2-Deoxy-D-glucose produced a higher peak acid response and peak gastrin level than insulin. The acid response to the stimulants was unrelated to the gastrin response. Insulin failed to increase gastrin level in three patients and 2-deoxy-D-glucose failed in one patient; both produced acid response in all patients. The absence of any relationship between gastrin level and acid secretion in the duodenal ulcer patients suggests that the acid response to insulin and 2-deoxy-D-glucose produced mainly by a vagal action on the parietal cells while gastrin exerts a permissive role.

3065 EFFECT OF ATROPINE ON INSULIN-STIMULATED GASTRIN RELEASE AND GASTRIC SECRETION OF ACID, PEPSIN, AND INTRINSIC FACTOR (IF). *(E.)* Schrumpf, E.; Vatn, M. H.; Semb, L. S. (Ulleval Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(7):665-669, 1974.

The effect of insulin and insulin combined with atropine on acid, pepsin, and intrinsic factor (IF) secretion was studied in duodenal ulcer patients to evaluate the cholinergic component of the insulin effect. Gastric secretion was collected for 1 hr basally and for 2 hr after insulin (0.2 IU/kg i.v.) or insulin combined with atropine (2 mg). The plasma gastrin level was determined radioimmunologically at 15-min intervals. In response to insulin, increased gastric secretion and increased plasma gastrin concentration were found. The simultaneous administration of atropine significantly reduced the secretion of acid, pepsin, and IF. Gastrin release was significantly enhanced. It is suggested that the insulin effect on acid, pepsin, and intrinsic factor secretion is cholinergic, whereas the insulin effect on gastrin release may be mediated through a non-cholinergic mechanism.

SMALL INTESTINE

3106 DUODENAL DUPLICATION AND ACUTE PANCREATITIS: A RARE COMBINATION. *(Fr.)* Meyer, C.; Otteni, F.; Kohler, J. J.; Hollender, L. F. (Univ. Hosp. Cent., Strasbourg, France). *Lyon Chir.* 70(4):255-256, 1974.

At laparotomy, radiological examination of the biliary tract of a 14-yr-old girl with acute pancreatitis showed a normal common bile duct and excellent flow into the duodenum, but some of the contrast medium escaped to the left side and outlined an area inside the pancreas. A bile-filled swelling the size of an adult fist was found in the head of the pancreas. It appeared to be either a cystic diverticulum of a bile duct or a pancreatic cyst. After performing a cystoduodenostomy, histological examination of the wall of the cyst revealed a duodenal mucosa surrounded by a layer of muscle, suggesting that this cavity resulted from duodenal duplication. It is suggested that this duplication compressed the pancreatic duct. The absence of signs referable to the biliary tract can be explained by communication of the opening at the bottom of the duplication with the lower bile duct and not with the pancreatic duct. Bile flowed into the diverticulum which acted as a reservoir. The patient is alive and well 17 months after surgery.

3107 PRIMARY INTESTINAL LYMPHOMA WITH PARAPROTEINEMIA. *(E.)* Shahid, M. J.; Alami, S. Y.; Nassar, V. H.; Balikian, J. B.; Salem, A. A. (American Univ. Hosp., Beirut, Lebanon). *Cancer* 35(3):848-858, 1975.

Five of 25 cases of primary intestinal lymphoma seen at the American University Hospital in Beirut in a 4-yr period are described, 4 of which (16%) were associated with immunoglobulin (Ig) abnormality. The main clinical features included abdominal pain, diarrhea, and marked weight loss, together with radiologic and some laboratory findings suggestive of malabsorption, with low levels of serum protein, serum albumin, serum cholesterol, and often serum calcium. Laparotomy performed in 4 cases revealed dilatation of the small intestine, with mesenteric node enlargement. In these 4 instances there was a definite histologic evidence of malignant lymphoma, either initially or later in the course of the disease. A characteristic feature was the diffuse infiltration of the intestinal mucosa with plasma cells, which in the deeper layers became progressively atypical and were mixed with histiocytes and giant cells. A similar infiltrate was seen in the mesenteric nodes. Immunoelectrophoresis showed the pattern of IgA heavy chain disease. It is suggested that IgA heavy chain disease is a variant of primary intestinal lymphoma and not a separate disease entity. From these cases, it may be stated that primary intestinal lymphoma with malabsorption, as seen in the Middle Eastern countries, represents a definite entity with characteristic clinical, radiologic, and histologic features.

3108 EXTRINSIC DUODENAL OBSTRUCTION IN INFANTS AND CHILDREN. *(E.)* Tryfonas, G.; Young, D. G. (R. Hosp. Sick Child., Glasgow, Scotland). *Br. J. Surg.* 62(2):125-129, 1975.

The case records of 34 infants and children (1 day to 11 yr) admitted to hospital during a 5-yr period with signs or symptoms due to extrinsic duodenal obstruction are reviewed. All the neonates had shown signs of an upper intestinal obstruction and all had vomited bile-stained fluid. Only two infants failed to pass meconium and most had passed changed stools. All the older infants and children, except one, had normal bowel habits until the acute episode. X-rays of the abdomen in the erect posture were not always helpful in making the diagnosis. When straight x-rays did not clarify the position, radiological studies using a contrast medium were made. An abnormal but variable pattern of gas distribution throughout the gut with fluid levels in the stomach, and sometimes in the duodenum and the small bowel when volvulus had occurred, were the most common findings. In infants or children with malrotation the duodenojejunal flexure was displaced to the right and the proximal small bowel was lying predominantly on the right side of the peritoneal cavity rather than on the left. Three types of malrotation were identified: 1) malrotation with bands; 2) malrotation with volvulus of the midgut; and 3) superior mesenteric artery obstruction. All the patients in this group were considered to require operation. Five patients died, one just after admission and four during the first 24 hr after operation. The factors which interrupt the normal rotation of the gut remain obscure. In only one of the present series was a clear etiological factor present, namely, a diaphragmatic hernia. It is emphasized that speed is essential in the diagnosis of this condition because there is no external evidence to indicate which infants have volvulus and this complication may result in gangrene of the small bowel.

3109 THE ABILITY OF AN ELEMENTAL DIET TO SUPPORT NUTRITION AND ADAPTATION IN THE SHORT GUT SYNDROME. *(E.)* Voitk, A. J.; Crispin, J. S. (Dep. Surg., Univ. Manitoba, Winnipeg, Canada). *Ann. Surg.* 181(2):220-225, 1975.

The usefulness of the elemental diet in the short gut syndrome was investigated using 80 adult male Sprague-Dawley rats which had been subjected to 85% enterectomy (sufficient to cause major nutritional problems) or jejunal biopsy. After recovery, the rats in each group were randomly fed either elemental diet or rat chow. Hemoglobin, albumin, and total protein were determined at the time of operation and at sacrifice, 8 weeks later. A daily record was also kept of weight, food and water consumption, and amount and character of stool. Biopsied rats gained more weight with elemental diet than chow (22% *versus* 18%). Resection produced greater weight loss than biopsy and slower gain. The failure to gain was most marked in elemental diet rats, significantly less than in the chow group by week 2. A fall in hemoglobin, protein, and albumin was seen in all rats: neither the fall nor difference between the groups was significant. Enterectomized chow rats ate 22% more than their controls, whereas the elemental diet group ate 10% less. Increase in bowel length after resection, equally divided between jejunum and ileum, was 21% with elemental diet and 26% with chow. Gut diameter after resection increased 104% and 98% with chow and elemental diet, resp. Villus height increased 65% in the jejunum of both enterectomized groups and 85% and 78% with chow and elemental diet, resp., in the ileum. Changes in gut length, diameter and villus height were significant in each group but not between groups. It is concluded that elemental diet can support nutrition in the adaptive phase of the short gut syndrome but less well than normal food.

3110 METASTATIC SEEDING ALONG THE SMALL BOWEL MESENTERY. ROENTGEN FEATURES. *(E.)* Meyers, M. A. (New York Hosp.-Cornell Univ. Med. Cent., N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(1):67-73, 1975.

The characteristic roentgen features in eight cases of proved malignant seeding along the small bowel mesentery are discussed and illustrated. The anatomic features of the small bowel mesentery and the pathways of flow of ascitic fluid along its peritoneal recesses determine the deposition and growth of seeded metastases. Seeded deposits lodge particularly within the lower recesses of the small bowel mesentery and are reflected by typical changes involving distal ileal loops or the cecum. These changes are characterized by palisading, arcuate scalloped deflections or gross mass displacement of distal small bowel loops in the right lower quadrant, or by extrinsic indentations upon the medial and inferior contours of the cecum. Associated desmoplastic reaction may result in tethering of mucosal folds and angulated fixation of bowel loops. The most extreme fibrous reaction was encountered in metastatic seeding from pancreatic carcinoma and mucin-producing gastric carcinoma. In the male, the primary carcinoma most commonly arises in the gastrointestinal tract and in the female, the genital system. It is concluded that the small bowel alterations are not difficult to distinguish from other common disease states. The lack of inflammatory features and the characteristic spectrum of changes help in the differential diagnosis from regional enteritis, tuberculosis, amebiasis, and peritoneal adhesions.

3111 ENDOSCOPIC POLYPECTOMY IN THE DUODENUM. ITS COMPLICATIONS BY PANCREATITIS. *(E.)*

Apler, E. I.; Foroozan, P.; Johnson, R. B.; Haubrich, W. S. (Scripps Clin. Res. Found., La Jolla, Calif.). *Gastrointest. Endosc.* 21(3):119-122, 1975.

The endoscopic removal of 9 of 12 duodenal polypoid lesions identified during an 18-month period is discussed. These lesions included epithelial and Brunner's gland adenomas, villous adenomas, and a carcinoid tumor. In all but one case, the lesion was first noted in upper gastrointestinal radiographs. The lesions were removed using the snare and electrocoagulation method, with intermittent current application. An attempt was made to avoid contact with the opposite duodenal wall. In two cases, the histopathological findings suggested that the procedure may have been of definite benefit. Two patients whose postbulbar adenomas were removed developed acute transient pancreatitis from which they recovered completely; their cases are presented in detail. The occurrence of acute pancreatitis in two members of this small group of patients may be cause for some hesitation with respect to future procedures. Both of these episodes involved lesions situated in the second portion of the duodenum which were endoscopically distinct and apart from the duodenal papilla. The following broad indications were drawn from this experience: 1) removal of a pedunculated lesion of the bulb which has some evidence of mucosal irregularity may be justified; and 2) masses which are submucosal and appear to be covered by normal duodenal lining might best be left alone.

3112 PANCREATIC ADAPTATION TO SUBTOTAL RESECTION OF THE SMALL INTESTINE IN INFANTS AND CHILDREN. *(Ger.)*

Niessen, K. H.; Brugmann, G.; Osswald, P.; Schmidt, K.; Flach, A. (Pediatr. Clin., Univ. Tubingen, Germany). *Klin. Wochenschr.* 52(16):796-798, 1974.

The secretin-pancreozymin test was used to study pancreatic function in 4 patients who had undergone subtotal resection of the small intestine 1 day to 1 month after birth for necrotizing enteritis (2 cases), volvulus of the small intestine (1 case), or gastroschisis (1 case). When calculated on the basis of body weight, the volume of pancreatic secretion and the bicarbonate output were increased in 2 of the 4 patients. In addition, 1 patient had an elevated trypsin output. However, when the absolute values of pancreatic secretion in these children were compared with those of 23 children of the same age who were of normal height and weight, both these values and values calculated on a body weight basis fell in the normal range. It is suggested that evidence of pancreatic hyperfunction in patients who have undergone subtotal resection of the small intestine, as in patients with celiac disease, is due to malnutrition in these children.

3113 CYTOPHOTOMETRIC AND AUTORADIOGRAPHIC STUDIES OF THE FUNDAL GLANDS OF THE GASTRIC MUCOSA AFTER EXTENSIVE RESECTION OF THE SMALL INTESTINE.

(Rus.) Zufarov, K. A.; Baibekova, E. M.; Pechnikov, L. V. (Tashkent Med. Inst., USSR). *Arkh. Anat. Gistol. Embriol.* 67(11):18-23, 1974.

Cytophotometric and autoradiographic studies were conducted on male albino rats after an extensive resection of the small intestine to measure DNA content in the nuclei of the chief and parietal cells of the fundic glands, RNA content in the cytoplasm of the chief cells, and ^{3}H-thymidine incorporation in all the epithelial cells of the gastric mucosa. The findings indicate that by the end of the first month, the pepsinogen-forming function of the fundic cells was significantly inhibited and partially replaced by mucus secretion, which was indicated by the drop in the DNA content in the cytoplasm of the chief cells by 16% and a twofold increase of the goblet cells, and decrease in the chief cells by 37%. The adaptive function was taken over by the nuclei of the chief and parietal cells of the stomach which was evidenced by an increase in the DNA content in these cells and a more active DNA synthesis in the parietal cell nuclei. Three months after the operation, enhanced DNA synthesis and proliferation of the chief cells indicated the postoperative tendency to regulate protein metabolism and rectify the deficiency of the pepsinogen secreting cells. It is suggested that resection of the small intestine involves an adaptive rearrangement resulting in enhanced synthesis of nucleic acids in the specialized cells of the fundic glands, in the increase of their number and mitotic activity.

3114 LEIOMYOMAS OF THE SMALL INTESTINE: TWO CASES DISCOVERED BY ARTERIOGRAPHY. *(Fr.)*

Labrune, M.; Brault, B.; Rey, J. L.; Chaput, J. C.; Gaux, J. C. (Antoine-Beclere Hosp., Clamart, France). *Ann. Radiol. (Paris)* 17(5):491-495, 1974.

The value of arteriography in the localization of leiomyomas of the small intestine was studied. Two patients presenting with recurrent digestive hemmorrhage showed arteriographic evidence of a benign tumor: normal or enlarged afferent artery; tumor formed from a mass of harmonious neovascularization; homogenous opacity of the parenchyma; normal afferent vein; spongy aspect to the tumor; and massive venous return when the leiomyoma is associated with an angiomatous component. In one instance, the tumor was located on the duodenum, and in the other it was located on the ileocecum. Treatment was by limited resection. Surgical exploration is necessary to determine the specific histologic type. Because the tumors tend to develop outside the intestinal lumen, barium opacification may produce normal appearance, although there may be signs of extrinsic compression, as in one of the observed cases. It is concluded that only arteriography can reveal the existence and position of these hypervascular tumors.

3115 THE ROENTGENOLOGIC SPECTRUM OF SMALL INTESTINAL CARCINOID TUMORS. *(E.)* Bancks, N. H.; Goldstein, H. M.; Dodd, G. D., Jr. (Univ. Texas Med. Sch., Houston). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):274-280, 1975.

The roentgenologic features of 18 small intestinal carcinoid tumors were analyzed. The patients, 8 of whom were female, ranged in age from 40-69 yr. The primary neoplasm arose in the ileum in 17 cases and in the jejunum in 1 case. The most common clinical symptom was crampy abdominal pain generally associated with some degree of intestinal obstruction. Roentgenologic appearances varied from solitary or multiple submucosal nodules to extensive mesenteric desmoplasia without demonstration of a tumor mass. Some manifestation of the desmoplastic reaction was observed in at least 13 patients. The spectrum of roentgenologic features secondary to carcinoid tumors was more diverse than with most gastrointestinal neoplasms, primarily because of the variety of growth patterns and the tissue reactions incited by this disease. Thus, carcinoid tumors should be considered in the differential diagnosis of both inflammatory and neoplastic small bowel lesions. In particular, when there is evidence of solitary or multiple submucosal nodules and/or when manifestations of mesenteric disease are present, carcinoid tumor is a likely diagnosis. Angiographically, the most common features of carcinoid tumors are kinking, irregularity, or obstruction of distal intra-mesenteric arteries. Careful small intestinal examination is essential, since a barium study often provides the first or only opportunity to suggest diagnosis. Moreover, prognosis appears to be directly correlated with the tumor size and resectability, and preoperative consideration of the diagnosis is important for safe anesthesia in patients with elevated vasoactive hormonal levels.

3116 DUODENAL PSEUDOPOLYP - THE FLEXURE FALLACY. *(E.)* Nelson, J. A.; Sheft, D. J.; Minagi, H.; Ferruci, J. T., Jr. (VA Hosp., San Francisco, Calif.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):262-267, 1975.

Several patients with a persistent roentgenographic contour defect at the superior flexure of the duodenum were surgically studied and followed for periods of 6 months to 15 yr. The typical finding was a characteristic filling defect with prominent folds in the duodenal bulb and no evidence of ulcer or mucosal erosion; the descending duodenum was normal. The explanation of the phenomenon appeared to be a heaping up of redundant loose mucosa on the inner aspect of the duodenal flexure; as the tubular muscle wall of the gut turned, the outer mucosa was stretched while the inner folds at the flexure were compressed and piled up. The phenomenon appeared to be both benign and rather common, occurring in males and females within a broad range of ages. Radiologists should become aware of this change, because it is so characteristic in location and appearance that further, more aggressive diagnostic work-up seems unwarranted.

SMALL INTESTINE

Malabsorption

3176 INCIDENCE OF CELIAC DISEASE. *(Fr.)* Bernier, J. J.; Bourdeloux, J. J. (St. Lazare Hosp., Paris, France). *Arch. Fr. Mal. App. Dig.* 63:361-364, 1974.

Celiac disease has been diagnosed in 90 adults and 299 children less than 15 yr old who were born in the Paris area between 1882 and 1972; 32% were males and 68% females. In all of these cases, diagnosis was confirmed by intestinal biopsies and regression of the disease after institution of a gluten-free diet. In the Paris area there is 1 case/75,000 adult inhabitants attending the hospitals in this study. Among children, the incidence was 1 case/5454 children living in Paris and 1 case/4138 children living in the Paris area. A more detailed study of children born in 1970-1972 who developed celiac disease before age 2 yr, showed 1 case/2500 births in the Paris area. Among North Africans, mostly Algerians, living in Paris, the incidence was much higher (1 case/250 children less than 15 yr old). An apparent increase in the incidence of celiac disease in children born between 1960 and 1968 and those born between 1970 and 1972 may be due to a difference in the incidence of symptomatic and asymptomatic forms.

3177 BILE ACID MALABSORPTION IN CHILDREN WITHOUT INTESTINAL RESECTIONS. *(Fr.)* Weber, A.; Roy, C. C.; Chartrand, L.; Morin, C. L.; van Caillie, M. (St. Justine Hosp., Montreal, Canada). *Union Med. Can.* 103(12):2089-2094, 1974.

Fecal lipids and bile acids were measured in 72-hr stool specimens from 87 children with a variety of gastrointestinal disorders and 18 controls. None of the patients had a history of hepatobiliary disease or intestinal resection. Bile acid malabsorption was detected in 1 of 6 children with Crohn's disease, 2 of 8 with refractory diarrhea, 3 of 4 with chronic specific diarrhea (2 with salmonellosis and 2 with giardiasis), all of 4 with bacterial contamination of the upper intestine due to intestinal stasis, and all of 36 patients with cystic fibrosis. No evidence of bile acid malabsorption was found in 16 children with celiac disease or 7 with irritable colon. These findings differ from those reported in the literature on adults with Crohn's disease and irritable colon. Intestinal transit was decreased to a comparable extent in children with irritable colon, celiac disease, and cystic fibrosis, although fecal excretion of bile acids was not increased in irritable colon or celiac disease. Thus, increased fecal bile acid contents cannot be explained by increased transit times in cystic fibrosis.

3178 STENOSIS OF THE SMALL INTESTINE ASSOCIATED WITH STAGNANT LOOP SYNDROME AND MALABSORPTION. *(Fr.)* Hurtubise, M.; Emond, M.; Rousseau, B. (Notre Dame Hosp., Montreal, Canada). *J. Can. Assoc. Radiol.* 25(3):227-233, 1974.

Case reports are presented for 3 patients with stagnant loop syndrome and malabsorption. A 50-yr-old woman who had undergone 2 ileotransversostomies over a 23-yr period for Crohn's disease developed malabsorption and steatorrhea. X-rays showed distension of the small intestine above the anastomosis. A 15-yr-old boy with a 1-yr history of diarrhea presented with growth retardation, ascites, edema of the lower extremities, and edematous infiltration of the abdominal wall. Laboratory investigations revealed severe malabsorption, steatorrhea, and severe hypoproteinemia. X-rays showed distension of about 100 cm of proximal small intestine which was 10 cm in diameter in the most severely affected part. At laparotomy, a stenotic segment of small intestine, about 35 cm long, was found below the distended segment. On the basis of ulcerations, epithelioid follicles, and occasional polynuclear eosinophils in this stenotic segment, a diagnosis of Crohn's disease was established, but sarcoidosis is also possible due to the presence of Schumann bodies. After removal of stenotic intestine, the patient showed marked improvement: malabsorption disappeared and he gained in weight and stature. A 21-yr old man with a 7-yr history of diarrhea presented with marked growth retardation and malabsorption. Laparotomy showed volvulus of the last loop of the small intestine around an adhesion, with traction being exerted between the cecum and last loop of the small intestine. Adhesions were removed, but the patient's recovery was complicated by a greatly distended loop of small intestine which showed no evidence of mechanical obstruction. The patient gradually improved after this was removed. Three biopsies of this small intestine ruled out the possibility of aganglionosis.

3179 ASSESSMENT OF SMALL BOWEL FUNCTION IN THE ELDERLY USING A MODIFIED XYLOSE TOLERANCE TEST. *(E.)* Webster, S. G. P.; Leeming, J. T. (Chesterton Hosp., Cambridge, England). *Gut* 16(2):109-113, 1975.

Small bowel function was measured in 85 elderly patients (63-95 yr old, mean age 81) irrespective of renal function by determining the ratio between the amount of xylose recovered in the urine after a p.o. dose and the amount recovered after i.v. administration. No patients with small bowel disease or suggestive symptoms were included nor were those with a diagnosed noeplastic lesion or ascites. A younger group ranging in age from 18-35 yr was also studied. Subjects were fasted for at least 8 hr after which they were given 25 g of d-xylose in 200 ml water p.o. or 5 g of xylose in a 10% solution injected slowly i.v. over 2-3 min. Urine was collected for 5 hr after xylose administration, the total volume measured, and analyzed for xylose. In 69 elderly patients without catheters, 5-hr urinary xylose recovery after the p.o. dose ranged from 0.1-7.3 g and after the i.v. dose ranged from 0.4-2.5 g. In 16 elderly patients with catheters, 5-hr urinary xylose recovery after the p.o. dose ranged from 0.7-6.5 g and after the i.v. dose from 0.5-2.4 g. Corresponding values in the 20 young controls were 3.7-9.0 g after the p.o. dose and 1.1-2.7 after i.v. administration. These findings indicate that the absorption of d-xylose from the small bowel is impaired in old age. The ability to absorb xylose was very variable in the aged subjects but 26% of those elderly subjects studied had a xylose test absorption ratio below the calculated normal range of the young subjects. In a previously published report it was concluded that absorption of xylose was not impaired in the elderly. There are two possible explanations for the difference between the earlier results and those reported in this paper: 1) the first group was younger than the group studied in the present report; and 2) no dietary restrictions were imposed on subjects undergoing the i.v. test in the previously reported study. It is concluded that poor renal function, incomplete bladder emptying, and altered gastric emptying are not possible causes for the differences between the two age groups.

3180 COMPUTER CARD MORPHOMETRY OF JEJUNAL BIOPSIES IN CHILDHOOD COELIAC DISEASE. *(E.)* Meinhard, E. A.; Wadbrook, D. G.; Risdon, R. A. (R. Free Hosp., London, England). *J. Clin. Pathol.* 28(2):85-93, 1975.

Histological changes in 95 jejunal biopsy specimens from children have been analyzed by a new morphometric technique. The microscope image of the specimen is traced directly onto computer data cards. A simple sketch records accurate quantitative data in a matrix of 840 points, retaining the spatial arrangement of the tissue components. Data are fed, *via* an optical mark data card reader, into a mini-computer. FORTRAN IV programs allow calculation of surface area, villous heights, and component volumes in metric units, and of volume proportions, volume:volume ratios, and surface:volume ratios. Pictorial and numerical printouts are produced, which are suitable for inclusion in the patient's notes. Jejunal biopsies from 37 controls and 26 untreated celiac patients were clearly distinguished morphometrically. Untreated celiac mucosae were flat; the surface area fell from a control value of 3.13 mm^2/mm^2 muscularis mucosae to 1.13 mm^2/mm^2 muscularis mucosae. The surface epithelial volume fell from 0.16 mm^3/mm^2 (or 34% of total mucosal volume) to 0.03 mm^3/mm^2 muscularis mucosae (or 8% of the total mucosal volume). The cumulative villus height fell similarly from 2942 μ to 50 μ. The crypt volume rose significantly in untreated celiac mucosa from control volume of 0.09 mm^3/mm^2 (21% of total mucosal volume) to 0.17 mm^3/mm^2 muscularis mucosae (39% total mucosal volume). The ratio of surface epithelial volume to crypt volume fell significantly from 1.74 in controls to 0.21 in untreated celiacs. The volumes of surface-related and crypt-related lamina propria show a pattern of changes similar to their respective epithelial components. When on a gluten-free diet, treated celiac children show few differences from controls. A return of dietary gluten causes a reversion of the results towards those of the untreated celiac group. It is noted however, that the total mucosal volume does not differ between the groups, suggesting that the mucosal lesion in celiac disease is not a true atrophy.

3181 IRON DEFICIENCY ANEMIA AND MALABSORPTION. *(Ger.)* Vetrella, M.; De Masi, V.; Tancredi,

F. (Santa Annunziata Hosp., Naples, Italy). *Monatschr. Kinderheilk.* 122(7):562-564, 1974.

Eight patients, aged 12-36 months, with iron-deficiency anemia and symptoms of intestinal malabsorption (diarrhea, pathological xylose-test, pathological test for fecal fat) were treated with parenteral doses of iron along with an otherwise unrestricted diet. A peroral biopsy showed partial to total atrophy of the mucosa in the small intestine of 7 of these 8 patients. Within 4 to 12 days after institution of parenteral treatment with iron, diarrhea ended; hematological parameters normalized within 3 weeks. The fat excretion normalized within 10 days to 4 months and the xylose test, within 1 to 2 months. The peroral biopses were normal 6 months after institution of treatment.

3182 CORRECTION OF THE MALABSORPTION OF THE PRETERM INFANT WITH A MEDIUM-CHAIN TRIGLYCERIDE FORMULA.

(E.) Roy, C. C.; Ste-Marie, M.; Chartrand, L.; Weber, A.; Bard, H.; Doray, B. (Sainte-Justine Hosp., Montreal, Canada). *J. Pediatr.* 86(3): 446-450, 1975.

The extent of fat malabsorption in preterm infants fed long-chain triglyceride diets and the effects of a medium-chain triglyceride formula on the steatorrhea and resultant caloric deficiency were investigated in 25 preterm infants weighing 1,300-1,800 g. After receiving a milk-based formula for 1 week, 16 infants were fed 2 isocaloric formulas containing either medium-chain or long-chain triglycerides for 15 days. The alternate formula was given for a second period of identical duration. In the second part of the study, 9 infants were given medium-chain triglycerides, and long-chain triglycerides in which the chloride concentration was that of the medium-chain triglyceride diet (21 mEq/liter). Nitrogen was measured in aliquots of formula, urine, and stools by the micro Kjeldahl method. Stool fat was determined by a technique which quantitatively extracted medium- and long-chain fatty acids. The assay of bile acids in feces was performed by a modification of the enzymatic method. Serum base excess, pH, total CO_2, sodium, potassium and chloride were also measured. While receiving the medium-chain triglyceride diet, the infants had greater percent fat absorption, as compared to 83.4% with the long-chain triglycerides (97.1%) and weight gain, 11.5 g/kg/100 calories and 7.5 g/kg/100 calories, resp. It is concluded that this study confirms both the presence of fat malabsorption in premature infants and the beneficial effects of a medium-chain triglyceride diet.

3183 THE EFFECT OF CHOLESTYRAMINE ON INTESTINAL ABSORPTION.

(E.) West, R. J.; Lloyd, J. K. (Inst. Child Health, London, England). *Gut* 16(2): 93-98, 1975.

The effect of long-term treatment with cholestyramine on the absorption of fat, vitamins, and some minerals was studied in children with familial hypercholesterolemia. Eighteen children were treated with cholestyramine (0.6 g/kg/day) for 1-2 1/2 yr, during which time various biochemical determinations were made. In patients treated for over 1 yr, the mean serum folate concentration decreased from 7.7 ng/ml to 4.4 ng/ml; a corresponding lowering of red cell folate was also observed. Oral folic acid (5 mg/day) overcame the deficiency. Prothrombin time remained normal in all patients. There was a significant decrease in the serum concentrations of vitamins A and E and of inorganic phosphorus over the first 2 yr of treatment, although the values remained within the normal range. Concentrations of serum iron, vitamin B_{12}, plasma calcium, and protein did not change significantly. Five of seven children eating normal diets had fecal fat of over 5 g/day while on cholestyramine; none had diarrhea or weight loss. There was no consistent relationship between dosage and fecal fat. The results of the study show no evidence that cholestyramine impairs absorption of iron or vitamin B_{12}, and the normal growth rate in children and the maintenance of plasma protein concentration provide further evidence of the safety of prolonged administration of cholestyramine.

3184 PTEROLYGLUTAMIC ACID MALABSORPTION IN TROPICAL SPRUE.

(E.) Corcino, J. J.; Coll, G.; Klipstein, F. A. (Univ. (Dist.) Hosp., San Juan, Puerto Rico). *Blood* 45(4):577-580, 1975.

Pteroylglutamic acid absorption was assessed in 10 untreated tropical sprue (20-62 yr old) and 8 control subjects using a marker perfusion technique. After an overnight fast, the subjects were perfused with an isosmotic solution containing 25 ng/ml of crystalline pteroylglutamic acid with either mannitol or glucose at a concentration of 55.6 mM and a pH of 7.2. Perfusion rate was 9.2 ml/min. Each subject was perfused on 2 consecutive days. Polyethylene glycol was used as a nonabsorbable marker. Pteroylglutamic acid was measured microbiologically using *Streptococcus fecalis*. Absorption of pteroylglutamic acid was 47.3% and 28.1% for the controls and tropical sprue patients, resp., using the mannitol solution. There was considerable overlap between % pteroylglutamic acid absorbed by both groups. When the same subjects were perfused with the glucose solution, pteroylglutamic acid absorption was 58.8% and 9.8% for the controls and tropical sprue patients, resp. A clear-cut separation was observed between both groups with differences in absorption significant to the $p<0.001$ level. These results confirm those of a previous study using marker perfusion techniques and indicate, in a larger number of subjects, that malabsorption of physiologic doses of pteroylglutamic acid is demonstrable in all subjects with tropical sprue when the appropriate techniques are used.

3185 SUBEPITHELIAL COLLAGEN IN INTESTINAL MALABSORPTION.

(E.) Bossart, R.; Henry, K.; Booth, C. C.; Doe, W. F. (R. Postgrad. Med. Sch., London, England). *Gut* 16(1):18-22, 1975.

Intestinal biopsies from 146 patients with adult celiac disease and 13 patients with intestinal villous atrophy of different etiology (seven with tropical sprue, four with Whipple's disease, one with hypogammaglobulinemia, and one with strongyloidiasis) were assessed for the presence of subepithelial collagen and compared with 20 controls. All sections were stained with hematoxylin and eosin and with hematoxylin van Gieson. A grading system was devised to assess the presence and amount of subepithelial collagen: grade 1, stainable collagen either absent or confined to the vicinity of the basement membrane; grade 2, a definite zone of subepithelial collagen which involved the subepithelial vessels, and which resulted in a thickened linear staining pattern; and grade 3, a thick irregular collagen band which extended into the lamina propria to variable depths. The amount of stainable collagen in biopsies from control subjects never exceeded grade 1. In 94 of 146 patients with adult celiac disease (64%), the biopsies also showed grade 1 staining. Forty-one patients, (28%) however, showed a grade 2 staining pattern and 11 (8%) showed grade 3. Grade 2 staining was seen in the biopsies from two tropical sprue patients and grade 3 in a third. The tendency of the epithelial layer to strip off over collagen bands and the focal nature of the fibrotic process even within a single biopsy were conspicuous histological features. The effect of treatment with a gluten-free diet was studied in follow-up jejunal biopsies of 51 adult celiac patients who had taken the diet for at least 6 months. In most cases the subepithelial changes regressed following treatment but no improvement occurred in three patients whose pre-treatment biopsies showed grade 3 changes despite prolonged gluten withdrawal. Two of these three patients died of unremitting malabsorption. The results of this study confirm that collagenous subepithelial thickening, sometimes extending deeply into the lamina propria of jejunal biopsies, is a common finding of adult celiac disease. Identical changes, however, were seen in biopsies from tropical sprue patients. Subepithelial collagen, therefore, is a non-specific finding probably related to an inflammatory reaction occurring in the region of the basement membrane.

3186 ENDOCRINE CELLS IN THE HUMAN JEJUNAL MUCOSA IN NORMAL SUBJECTS AND PATIENTS WITH CELIAC SPRUE.

(Cz.) Lojda, Z.; Fric, P. (1st Inst. Pathol. Anat., Charles Univ., Prague, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 28(1):1-10, 1974.

Peroral biopsies of the jejunal mucosa, obtained from 15 patients with celiac disease and 12 normal subjects, were examined under the electron microscope and with a variety of histochemical tests. On the basis of the size and shape of the granules they contained, endocrine cells were classified into four groups. Enterochromaffin (EC) cells, which constituted more than half of the endocrine cells, had very dense, polymorphic granules measuring 200-600 nm. L-cells were the second most common type; their granules were large (200-400 nm) and round and were somewhat less dense than granules in EC-cells. S-cells were not found as often and contained small (100-250 nm) round granules; in some cases, it was impossible to differentiate S-cells from L-cells. D-cells were present in small numbers in only three biopsies and contained round granules, measuring 300-400 nm, of low density which resembled granules in the D-cells in the islands of Langerhans. All four types of endocrine cells were found in contact with the intestinal lumen. The free surface of these cells were always equipped with microvilli which were smaller than those of the enterocytes and a poorly developed glycocalyx. The presence of pinocytotic vacuoles below the microvilli indicates that the surface from which microvilli project is involved in the absorption of material from the intestinal lumen. EC-cells could be differentiated from other endocrine cells by histochemical methods on material fixed with formol or glutaraldehyde, while L-, S-, and D-cells could be detected on frozen sections of unfixed tissue. Biopsies from six patients with celiac disease contained larger than normal numbers of both EC- and L-cells. Endocrine cells more often bordered the lumen than in biopsies from normal subjects. Vacuoles, the size of which corresponded to those of specific granules, were present in larger than normal numbers, particularly in L-cells. This finding is interpreted as an increase in the release of the contents of these granules. Emiocytosis was not observed in any type of endocrine cell, either in normal subjects or in patients with celiac disease.

3187 ENZYME ACTIVITIES AND PROPERTIES OF LYSOSOMES AND BRUSH BORDERS IN JEJUNAL BIOPSIES FROM CONTROL SUBJECTS AND PATIENTS WITH COELIAC DISEASE.

(E.) Peters, T. J.; Heath, J. R.; Wansbrough-Jones, M. H.; Doe, W. F. (R. Postgrad. Med. Sch., London, England). *Clin. Sci. Mol. Med.* 48(4): 259-267, 1975.

The properties and enzymic activities of lysosomes in normal human intestinal mucosa and in mucosa from patients with untreated and treated (by dietary gluten withdrawal) celiac disease were studied. All 4 brush border enzymes (leucyl β-naphthylamidase, alkaline phosphatase, β-galactosidase, and α-glucosidase) were significantly depressed in the jejunal biopsy specimens from the untreated celiac disease patients; the decrease was particularly striking for brush-border β-galactosidase. In the treated celiac group, the enzyme activities returned toward normal values, paralleling morphological and functional improvement. The mean activities of *N*-acetyl-β-glucosaminidase, β-galactosidase, acid phosphatase, acid diesterase, acid-β-galactosidase, and β-glucuronidase were significantly increased in the untreated celiac patients, the activities decreasing toward normal values in the treated patients. The cytosol enzyme lactate dehydrogenase showed a significant decrease in the untreated celiac mucosa with a return to normal activity after treatment. Measurement of brush-border integrity by differential centrifugation of biopsy extracts indicated increased fragility of the brush borders in the untreated patients; the treated patients showed normal values. Assessment of lysosomal integrity by assay of latent *N*-acetyl-β-glucosaminidase and the sedimentable activity of 4 acid hydrolases demonstrated increased lysosomal fragility in the untreated celiac mucosa and normal values in the biopsies from the treated patients. The results indicate that the microvilli of celiac enterocytes are more fragile than normal, that the lysosomes play a role in the pathogenesis of the enterocyte damage in celiac disease, and that the pathogenesis of the disease is related to a toxic effect of gluten or an immunological mechanism.

3188 EFFECT OF PANCREATIN ON VITAMIN B$_{12}$ MALABSORPTION IN PATIENTS WITH TOTAL PANCREATECTOMY. *(E.)* Morishita, R.; Fujii, M.; Yamamoto, T.; Wakisaka, G.; Matsumoto, Y.; Ono, H. (Kyoto Univ. Sch. Med., Japan). *Digestion* 11(3/4):240-248, 1974.

The effect of pancreatin on vitamin B$_{12}$ absorption was studied in 3 patients who had undergone total pancreatectomy for cancer, 3 patients who had undergone partial pancreatectomy (1 in which the stomach was totally extirpated), and 1 patient with pernicious anemia. B$_{12}$ absorption was measured using a whole body spectrometer before, 35 min after, and 7 days after the oral administration of 0.2-0.3 μg ^{60}Co-B$_{12}$ (specific activity 0.73-0.8 or 2-3 μCi/μg). Marked B$_{12}$ malabsorption was observed in all patients who had undergone total pancreatectomy, the patient who had undergone total gastrectomy and partial pancreatectomy, and the patient with pernicious anemia. B$_{12}$ absorption was normal or somewhat depressed in the other 2 cases of partial pancreatectomy. In 2 cases of total pancreatectomy, administration of 12 g pancreatin markedly improved B$_{12}$ absorption. In the third case, pancreatin in conjunction with normal human gastric juice brought about a marked improvement in B$_{12}$ retention; the gastric juice in this patient revealed achlorhydria. Pancreatin did not enhance B$_{12}$ absorption in the partial gastrectomy or pernicious anemia patients. The beneficial effect of pancreatin on B$_{12}$ absorption in the total pancreatectomy cases was reduced by heating at 100 C for 10 min. B$_{12}$ retention in the 2 cases of partial pancreatectomy was decreased by pancreatin administration. Fat absorption was improved by the administration of small amounts of pancreatic enzymes in 2 cases of total pancreatectomy, 1 of which had not shown improved B$_{12}$ absorption after pancreatin alone. Exocrine secretions of the pancreas were severely inpaired in the patients with pancreatic disorders. The results do not clarify the mechanism by which pancreatic extract improves B$_{12}$ absorption in patients with exocrine pancreatic insufficiency.

3189 THE ROENTGENOGRAPHIC AND CLINICAL FINDINGS IN WHIPPLE'S DISEASE: A REVIEW OF 8 PATIENTS. *(E.)* Philips, R. L., Carlson, H. C. (Mayo Clin., Rochester, Minn.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):268-273, 1975.

The clinical and roentgenographic findings in 8 patients (6 men and 2 women; average age at diagnosis 53 yr) with Whipple's disease are reported. Seven patients had abnormal roentgenograms with coarse folds and slight dilatation of the small bowel. Measurement of the mucosal folds and jejunal and duodenal width indicated thickening. The eighth patient showed no roentgenographic abnormalities. All patients had watery diarrhea and had undergone weight loss, and arthralgia was present in 7 cases. There were few physical signs, but lymphadenopathy, pigmentation, perifollicular purpura, and/or edema were present in some patients. All patients had decreased levels of serum albumin and 7 had excessive losses of fat in the stool. Periodic acid-Schiff positive macrophages in the cytoplams of the jejunal mucosa were invariably present on biopsy. All patients were treated with tetracycline (250 mg 4 times/day), which resulted in slow but steady improvement. All repeat roentgenograms and biopsy specimens showed evidence of improvement in the small bowel. The roentgenographic findings in Whipple's disease are nonspecific and resemble those of other causes of malabsorption. Positive identification of the disease is probably not possible roentgenographically, small bowel biopsy being necessary to confirm its presence.

3190 A FAMILY STUDY OF COELIAC DISEASE. *(E.)* David, T. J.; Ajdukiewicz, A. B. (Bristol Gen. Hosp., England). *J. Med. Genet.* 12(1):79-82, 1975.

The genetic mechanisms involved in the hereditary transmission of celiac disease were investigated in a family study of 141 cases on biopsy proven celiac disease in southwestern England. Thirteen patients (9%) had a positive family history of celiac disease involving a total of 21 affected relatives. Of the 13 cases with a positive family history, 4 were children. In 5 families, only a parent and child were affected, and vertical transmission through 3 generations was seen in a 6th family. In 5 additional families, only 2 sibs were affected; 4 of the sib pairs were of the same sex and there was one concordant set of monozygotic female twins. Of the 141 cases originally studied, 95 were female; the preponderance of females was absent among the childhood cases, but 99% of the adults were female. The pattern of inheritance in the 13 families with repeated celiac disease is compatible with an autosomal dominant gene with incomplete penetrance. However, other possibilities are not ruled out; a common recessive gene requiring an environmental factor for the disease to appear in homozygotes; polygenic or multifactorial inheritance; or multiple causation with forms inherited in various ways.

3211 AN INVESTIGATION INTO THE ENZYME HISTOCHEMISTRY OF ADENOCARCINOMAS OF HUMAN LARGE INTESTINE AND OF THE TRANSITIONAL EPITHELIUM IMMEDIATELY ADJACENT TO THEM. *(E.)* Marsden, J. R.; Dawson, I. M. P. (Dep. Pathol., Univ. Nottingham, England). *Gut* 15(10):783-787, 1974.

The enzyme histochemical patterns of normal colon, colonic adenocarcinoma, and the mucosa immediately adjacent to a carcinoma were studied to determine enzymatic changes in the adjacent epithelium, which might differ from those in the carcinoma and the more distant normal mucosa. Samples of the tissues were prepared for microscopic examination and stained using specific enzyme techniques; the enzymes were quantitated visually according to their depth of staining. Monoamine oxidase activity was moderate in normal mucosa, high in transitional mucosa, and low in carcinoma. Succinate dehydrogenase activity was high in transitional mucosa and low or moderate in normal and carcinomatous mucosa. Glucose-6-phosphate dehydrogenase activity showed a gradation from low in normal mucosa to high in carcinoma, while acid phosphatase showed the reverse of that pattern. The tetrazolium reductase activity was low or moderate in normal and transitional mucosa and high in carcinoma. Based on these findings, a combination of enzyme techniques and techniques for mucosubstances are suggested for detecting malignant transformation in benign lesions, or in detecting precancerous change in histologically normal mucosa in a vulnerable population.

3212 OPPORTUNISTIC INFECTIONS IN COLON CARCINOMA. *(E.)* Keusch, G. T. (Mt. Sinai Sch. Med., City Univ. New York, N.Y.). *Am. J. Clin. Nutr.* 27(12):1481-1485, 1974.

The problem of infections occurring in the patient with colonic carcinoma are reviewed. For many reasons the patient with large bowel cancer becomes a compromised host. The classical symptoms of the disease result from invasive, fungating tumors or annular constricting lesions which often result in ulcerations of the intestinal mucosa, thus providing a direct route of access for invasion by intestinal microflora. The tendency for colonic neoplasms to remain undiagnosed for long periods of time also allows considerable growth and frequent metastases to lymph nodes and liver may result in severe anorexia and cachexia. Chemotherapy may add to the appetite depression of the tumor itself and decrease the adequacy of nutritional intake of the host. Protein malnutrition, from which profound immunological abnormalities result, may be observed. Severe toxicity may result from the concomitant use of 5-fluorouracil and high voltage radiotherapy. For these and other reasons the colonic cancer patient is compromised toward opportunistic infections. Nevertheless, these patients are not unduly susceptible to protozoan and fungal agents. They may become infected with members of the normal bacterial flora of the gut which are provided with a site for penetration of the colonic mucosal barrier by the invasive or necrotizing tumor. *Bacterioides sepsis*, *Clostridium septicum* and other clostridial infections (in the absence of deep traumatic lesions), and left perinephric abscess caused by coliforms and fecal streptococci appear to be characteristic associations with colonic neoplasia. It is stressed that subcutaneous abscess of the left perinephric abscess due to bowel flora must always be investigated to determine the portal of entry. Colonic carcinoma will be present in a significant number of cases. In the absence of a known colonic lesion, diagnostic workup should be performed in all such patients. In fact, a presumptive diagnosis of a splenic flexure lesion can be made in patients with a left perinephric abscess due to coliform bacilli. Barium enema is indicated in older patients with bacterial endocarditis in whom the portal of entry of the organism was not known.

3213 DIET AS AN ETIOLOGICAL FACTOR IN THE DEVELOPMENT OF CANCERS OF THE COLON AND RECTUM. *(E.)* Howell, M. A. (Natl. Cancer Inst., Bethesda, Md.). *J. Chronic Dis.* 28(2):67-80, 1975.

Food consumption studies, both national and international, were compared to a Japanese case control study to investigate relationships between meat consumption and bowel cancer. The Japanese study used bowel cancer patients and hospital controls matched on age, race, and sex. Total meat use differentiated cases from controls. Beef had the highest relative risk, while chicken and some sources of pork had insignificant relative risk. For the international food consumption data from 37 countries, food figures for beef and veal, total meat, and all food were correlated with mortality and incidence rates. In the U.S. food consumption data, 900,000 people filled out questionnaires on how many times per week they ate 16 different food types. Findings from the international data showed vegetable food sources to be independent or negatively related to intestinal or colonic cancer. All food sources other than vegetables showed high positive relationships. Highest correlations were from per capita consumption of total meat and fat from all food sources. Factor analysis showed that foods associated with the highest mortality rates for colon, breast, and prostate were sugars, meats, eggs, milk and fats. In the U.S. study, no diet items were found to be associated with bowel cancer. In a 1948 study by the Dep. of Agriculture, however, food consumption differences were found for geographical areas and races, which contrasted in bowel cancer mortality or incidence rates. The 1947 incidence rates were 24.6/100,000 in San Francisco, and 17.6/100,000 in Birmingham, while these 2 cities were highest and lowest resp. in consumption of beef, veal and lamb. Results suggest that meat, particularly beef, is associated with malignancy of the large bowel.

3214 CARCINOEMBRYONIC ANTIGEN AND PROGNOSIS IN PATIENTS WITH COLON CANCER. *(E.)* Gerfo, P. L.; Herter, F. P. (Coll. Physicians Surg., Columbia Univ., New York, N.Y.). *Ann. Surg.* 181(1): 81-84, 1975.

Carcinoembryonic antigen serum levels were compared before and after surgery for carcinoma of the colon. One hundred fifty patients with non-metastatic carcinoma were followed for 24-36 months after colonic resection. Antigen levels greater than 4.0 ng were considered to be elevated. Patients were divided according to Duke's classification of tumor invasiveness into stages A, B and C in increasing severity. High preoperative antigen levels were found in 4 of 25 stage A patients, 25 of 61 stage B, and 39 of 64 stage C. Of the patients who died or survived uncured, 57% had high levels, while only 32% of those successfully cured had high levels. Three of 5 in stage A who died or were uncured had high levels, while 53% of those in stage B, and 70% of those in stage C, who died or were uncured had high levels. In contrast, of those who were cured, only 1 in stage A, 36% in stage B, and 40% in stage C had high levels. It is concluded that high carcinoembryonic antigen levels are correlated with the extent of the disease, and high preoperative levels are associated with poor prognosis.

3215 SPIRAL-SHAPED ORGANISMS ON THE SURFACE COLONIC EPITHELIUM OF THE MONKEY AND MAN.

(E.) Takeuchi, A.; Jervis, H. R.; Nakazawa, H.; Robinson, D. M. (Walter Reed Army Inst. Res., Washington, D.C.). *Am. J. Clin. Nutr.* 27(11):1287-1296, 1974.

Intestinal spirochetosis was studied in 221 healthy Rhesus monkeys and in specimens from 598 patients by histology, histochemistry, transmission and scanning electron microscopy. Of the 221 monkeys, 31 (14.0%) were massively infected by spiral organisms in the colon, 19 (8.5%) were infected in both colon and rectum and 12 (5.5%) were diffusely infected from cecum to rectum throughout, for an overall incidence of 28%. There were 210 colonic specimens from human subjects, of which 4 were affected by intestinal spirochetosis, 2 of which were associated with adenomatous polyp and the remaining 2 represented normal colonic mucosa. Of the 388 appendices from human subjects, 8 cases (2.1%) showed intestinal spirochetosis. Only 1 specimen showed mild acute appendicitis; the remaining 7 were normal. There were no significant gastrointestinal symptoms with the exception of 2 cases, 1 had a related history of epigastric discomfort and dyspepsia and the second had fever and right lower quadrant pain, symptoms which appear attributable to cholelithiasis and acute appendicitis, resp. The morphologic and ultrastructural findings of this study indicate that the characteristics of intestinal spirochetosis in the rhesus monkey and man are essentially identical in both species. Spiral organisms stained with hemotoxylin and eosin appear as broad basophilic haze on the colonic surface and are strongly positive by Warthin-Starry (silver) stain. Spiral-shaped organisms included 2 structurally different organisms, spirochetes and flagellated microbes. They intimately populated the brush border region of the surface of the colonic epithelium. They were absent in the crypt and small intestine. Infestation produced no alterations of cytocomponents of the underlying host structures. From the observations of this study it is evident that under certain conditions of local microenvironment, spiral microbes may invade the gut mucosa. It is suggested that, when such mucosal penetration occurs in large numbers, it can cause structural alteration and clinical symptoms in the host.

3216 ERRORS IN THE DIAGNOSIS OF CANCER OF THE COLON IN YOUNG PEOPLE.

(Rus.) Parakhoniak, V. I. (Gorki Med Inst., USSR). *Khirurgiia (Mosk.)* (1):107-111, 1974.

Retrospective studies of 340 patients treated between 1950 and 1971 for cancer of the colon showed that 64 (33 males, and 31 females) were 20-40 yr of age (one patient was 5 yr old). The study revealed a high incidence of diagnostic errors. Only 19 of the 64 patients (30%) were diagnosed properly. Radical surgery could be performed only on 39 patients (61%). Histological examination showed that 33 patients had adenocarcinomas; four mucous cancer; and two solid cancer. The 5-yr survival was recorded in 17 patients, which accounted for 48.6% of radical operations. A case is reported of a 34-yr-old man treated for over 1 yr for chronic hyperplastic gastritis and intercostal neuralgia. The patient was hospitalized with acute abdonimal pain and high fever. The case was successively diagnosed as dysentery, pancreatitis, perigastritis, hyperplastic gastritis and staphylococcosis of the bile ducts. Endoscopic examination finally revealed an intestinal stenosis at the splenic flexure. The surgery found a 15 cm x 15 cm tumor which penetrated into the diaphragm, thoracic wall, retroperitoneal space, the greater curvature of the stomach and the pancreas. Metastases were observed. The patient was pronounced inoperable. It is suggested that a clinical feature of cancer of the colon in young people is vague symptoms in the early stage of the disease.

3217 THE EFFECT OF WHEAT BRAN ON INTESTINAL TRANSIT.

(E.) Payler, D. K.; Pomare, E. W.; Heaton, K. W.; Harvey, R. F. (Malvern Coll., Worcs, England). *Gut* 16(3):209-213, 1975.

A controlled study was carried out on the effect of bran upon intestinal transit to exclude possible psychological effects. Transit time was determined in 20 healthy volunteers before and after the addition of bran to their diet; transit time was taken as the time required to pass 20 of 25 radiopaque pellets. After the addition of approximately 20 g bran/day to the diet, transit time fell from 2.75 to 2.0 days. Transit became faster in nine subjects who had an initial time 3 days or more, and in 3 of 7 with an initial time of 2 days, but became slower in four with an initial transit of 1 day. Frequency of defecation was not related to transit time and did not increase significantly with bran. In 10 additional volunteers with initial transit of 3-4 days, the effect of bran was compared with than of an equal volume of ground oatflakes. Bran caused a significant acceleration of transit, whereas oatmeal had no effect. The results confirm that wheat bran accelerates intestinal transit when transit is initially 3 days or longer, and the effect is likely due to the high content of cellulose and hemicelluloses in the bran; it may also slow down fast transit.

LARGE INTESTINE

Ulcerative Colitis

3290 THE SIGNIFICANCE OF ELEVATION OF SERUM CARCINOEMBRYONIC ANTIGEN (CEA) LEVELS IN INFLAMMATORY DISEASES OF THE INTESTINE. *(E.)* Booth, S. N.; King, J. P. G.; Leonard, J. C.; Dykes, P. W. (Med. Sch., Univ. Birmingham, England). *Scand. J. Gastroenterol.* 9(7):651-656, 1974.

Serial CEA measurements were made over a 12-month period in 133 patients with ulcerative colitis, 139 patients with Crohn's disease, 10 with diverticular disease and 20 with adult celiac disease. Elevated CEA levels occurred in ulcerative proctocolitis (9%), Crohn's disease (22%), and in one patient with diverticular disease. In Crohn's disease there was a significant increase in the number with persistent elevations when the history was longer than 10 yr. No significant relation to either duration or extent of disease was noted in ulcerative colitis. Transient elevations were often associated with exacerbations of the disease process. In 2 patients with ulcerative proctocolitis and in one with Crohn's disease, persistently abnormal CEA levels were associated with markedly abnormal liver function tests and abnormal hepatic biopsies. However, in 4 others with ulcerative colitis and hepatic involvement, serum CEA concentrations were normal. A rising value of 25 ng/ml was noted in one patient with completely resected Crohn's disease, but in whom steatorrhea was noted later to be associated with bacterial contamination of the small bowel and extensive jejunal diverticulosis. It is postulated that bacterial action results in enzymatic degradation of normal gastrointestinal cellular degradation products to produce or uncover an antigenic determinant identical to that on the CEA molecule. Two patients with ulcerative colitis developed a complicating carcinoma and both had normal CEA levels. It is concluded that, although CEA measurements may be valuable in cancer follow-up and possibly in the undiagnosed patient, they do not currently look promising as an indicator of malignant complications in inflammatory bowel disease.

3291 STUDIES OF LACTIC DEHYDROGENASE CONTENT IN RECTAL MUCOSAL BIOPSIES. *(E.)* Hunt, P. S.; Dennis, P. M.; Jablonski, P.; Khoo, S. K.; McLeod, L.; Thomson, H. D. P.; Watts, J. M. (Prince Henry's Hosp., Melbourne, Australia). *Gut* 15(12): 972-976, 1974.

The total lactic dehydrogenase content and lactic dehydrogenase isoenzyme ratios were studied in homogenized rectal mucosa from 31 patients with established non-specific mucosal ulcerative colitis and from 16 normal subjects. The 31 patients included 16 males and 15 females, aged 21-72 yr, of whom 14 had active rectal disease and 17 had mild or inactive disease. Of the 14 with active disease, 8 had chronic ulcerative colitis and 6 had ileo-rectal anastomosis. The total lactic dehydrogenase content was significantly increased in patients with active ulcerative colitis when compared with patients with inactive ulcerative colitis or with normal subjects. There was a similar though not a significant increase in the slow moving isoenzymes of lactic dehydrogenase in samples of rectal mucosa from patients with active colitis. The lactic dehydrogenase isoenzyme pattern was in the normal range in 2 of the 3 patients with histological premalignant changes in rectal biopsy specimens. There was a statistically significant linear correlation between the total lactic dehydrogenase content of rectal mucosa and the carcinoembryonic antigen levels in whole serum. Both the total content and isoenzyme ratios of lactic dehydrogenase were increased in neoplastic tissue obtained from patients with carcinoma of the colon and with tissue from benign rectal polyps. It is suggested that the increased lactic dehydrogenase content may be an expression of an oxygen deficit in the mucosal cells of patients with acute ulcerative colitis, rather than an index of premalignancy.

3292 SEQUELAE OF COLECTOMY AND ILEOSTOMY: COMPARISON BETWEEN CROHN'S COLITIS AND ULCERATIVE COLITIS. *(E.)* Steinberg, D. M.; Allan, R. N.; Brooke, B. N.; Cooke, W. T.; Alexander-Williams, J. (Gen. Hosp., Birmingham, England). *Gastroenterology* 68(1):33-39, 1975.

A comparison was made between the immediate and long term mortality of colectomy and ileostomy performed in 73 patients with Crohn's colitis and 442 patients with ulcerative colitis. In Crohn's disease the immediate mortality is 4%. In ulcerative colitis it is 10%, chiefly because of the higher proportion of emergency operations in the latter disease. The late mortality in both groups is 10%, though for different reasons. Complications due to recurrent disease are a major factor in causing death of patients with Crohn's disease. Disseminated malignancy of the colon was the principal cause of late death after excisional surgery for ulcerative colitis. A further comparison was made between the postoperative course of the 64 surviving patients with Crohn's disease and a comparable sample of 65 patients who had an ileostomy for ulcerative colitis in the same time period. There was a similar incidence of postoperative septic complications in the two groups, 35%. The readmission rate was twice as high in the Crohn's disease patients. Ileostomy reconstruction for mechanical complication was required in 21 patients with Crohn's disease, compared with 6 with ulcerative colitis. Further ileal resection was necessary for recurrent disease on another 25 occasions in the patients with Crohn's disease, but never in those with ulcerative colitis. Long term review graded the clinical status as excellent or good in 70% of those with Crohn's disease compared with 95% with ulcerative colitis. These results do not condemn the operation of colectomy and ileostomy for Crohn's disease, but excisional surgery is not recommended with the same optimism as for patients with ulcerative colitis.

3293 AZATHIOPRINE IN ULCERATIVE COLITIS: FINAL REPORT ON CONTROLLED THERAPEUTIC TRIAL. *(E.)* Jewell, D. P.; Truelove, S. C. (Radcliffe Infirm., Oxford, England). *Br. Med. J.* 4(5945):627-630, 1974.

Eighty patients, all suffering from a frank clinical attack of ulcerative colitis, were part of a controlled therapeutic trial of azathioprine. The attack was treated with a standard course of corticosteroids. For outpatients, oral prednisolone was given 5 mg four times a day and prednisolone disodium retention enema nightly. The inpatients were given prednisolone 21-phosphate 40 mg/day in the i.v. fluid, tetracycline 1 g/day in divided doses in the i.v. fluid, and rectal drip of hydrocortisone hemisuccinate sodium 100 mg twice daily. If clinical response was good, feeding was resumed and oral prednisolone, 40 mg/day was given in divided doses. When discharged the patients were placed on the outpatient regimen. In addition to this standard corticosteroid course, the patients were immediately placed on treatment with either azathioprine in a dose of 2.5 mg/kg or dummy tablets. Trial tablets were continued for 1 yr. If a patient relapsed, a further course of corticosteroids was given without interrupting maintenance treatment with azathioprine. During azathioprine, side effects were few and not dangerous. No example of frank bone-marrow supression was noted. One patient developed nausea, abdominal discomfort, and diarrhea. One developed a generalized erythematous rash. Patients on azathioprine had a greatly reduced production of plasma cells and K cells. In the treatment of an actual attack of ulcerative colitis, results indicate that no benefit came from adding azathioprine to the standard corticosteroid therapy. Patients admitted in their first attack showed no benefit from the 1 yr maintenance with azathioprine, the benefits of which were confined to patients admitted in a relapse of established disease. Even in these, the difference between treated and control patients failed to reach statistical significance, but the difference was great enough to suggest there is a prima facie case for regarding azathioprine as of some benefit in this group of patients.

3294 ELECTRICAL POTENTIAL DIFFERENCE AND ABSORPTION OF WATER, SODIUM, AND POTASSIUM BY THE TERMINAL ILEUM OF ILEOSTOMY PATIENTS. *(E.)* de Moraes Filho, J. P.; Salas-Coll, C.; Blendis, L.; Edmonds, C. J. (Cent. Middlesex Hosp., London, England). *Gut* 15(12):977-981, 1974.

Measurements of electrical potential difference and of absorption by a dialysis method were carried out in the terminal ileum of 11 patients (7 males and 4 females, aged 24-54 yr) with an ileostomy. The studies were performed between 2 weeks and 6 yr after formation of the ileostomy. In 6 patients the potential difference measured 3 cm from the ileostomy stoma showed a mean of 14.3 mV, compared to a mean of 9.2 mV when measured at 10 cm from the stoma. The potential difference thus appeared to be significantly increased close to the stoma. In 5 patients the potential difference was measured repeatedly over a period of 8 months with very little variation observed. The time for which the ileostomy had been established also appeared to have little effect on the potential difference. The measured potential difference increased considerably when glucose was added to the luminal solution, even though osmolality was kept constant. The effect was reversed rapidly when the glucose-containing solution was removed. A concentration of 10 nM/liter of glucose had little effect, while a maximum effect was achieved with 40 nM/liter. In 11 subjects in the presence of glucose the potential difference had a mean value of 18.7 (SEM), while without glucose the value was 8.3 (SEM). Reducing the luminal sodium concentration from 130 to 13 nM/liter was consistently associated with a fall of potential difference from a mean of 9.4 to 2.1 mV, which reversed when sodium was reintroduced. With a saline bicarbonate solution (sodium 145 or 140 mEq/liter, K 5, or 10 mEq/liter) in the dialysis tube, considerable absorption of fluid and sodium was demonstrated with little change in sodium concentration. Potassium secretion occurred with the lower, and absorption with the higher, concentration. The final luminal potassium concentration reached was consistent with a passive distribution between blood and lumen. It was concluded that the ileal mucosa, beyond the first few centimeters of the stoma of an ileostomy, behaves similarly to the ileum of the intact gut in regard to potential difference, water, sodium, and potassium transport. The relatively simple methods available for study of the accessible part of the ileum after ileostomy, offer a useful means of examining the action of drugs and hormones and of testing the functional state of the ileum epithelium.

3295 IMPAIRMENT OF 'ILEOSTOMY ADAPTATION' IN PATIENTS AFTER ILEAL RESECTION. *(E.)* Hill, G. L.; Mair, W. S. J.; Goligher, J. C. (Gen. Infirm., Leeds, England). *Gut* 15(12):982-987, 1974.

Ileostomy adaptation was studied in 10 patients (4 women and 6 men, aged 26-63 yr) diagnosed with granulomatous disease (4) or ulcerative colitis (6). Ileostomy and proctocolectomy were performed on 8 patients, 3 of whom also underwent ileal resections. Ileostomy, right hemicolectomy, and ileal resections were performed on the remaining 2. For the group as a whole, there was no significant decrease in the ileostomy volume over the 6-month period, nor was any significant intestinal adaptation uncovered by i.v. saline loading. However, marked difference in the mean daily fecal output of resected patients was noted. For nonresected patients the mean daily fecal output during postoperative days 7-11 was 456 ml compared with 909 for resected patients. At 6 months the low daily fecal output of 430 ml for the nonresected group was significantly different from the high output of 1105 ml for resected patients. Although there was no response to i.v. saline loading in the resected group, there was a significant increase in the mean daily fecal volume in nonresected patients, from 430 to 553 ml. This indicates that the resected group not only had a higher mean daily fecal volume from the outset, but also that no meaningful adaptation of the intestine had occurred in the 6 months. Patients in whom the terminal ileum was preserved had not only a smaller volume ileostomy from the outset, but at 6 months intestinal adaptation was noted when the extracellular fluid volume was rapidly expanded by i.v. saline loading. Whereas there was a significant thickening of the ileostomy fluid after 6 months in patients with low volume ileostomies, no such decrease in water content was noted in those with a high volume ileostomy. There was no apparent conservation of sodium in either group over the 6 months, but after i.v. saline there was a significant increase in daily output and concentration of sodium in nonresected patients. The daily fecal output of potassium was not significantly different for any of the time periods or between either group. After 6 months, the sodium:potassium ratio in the urine was lower for resected patients, suggesting this group was conserving sodium more than the nonresected patients. The reverse is true for feces. Whereas urine conservation of sodium occurs at the renal tubule in the resected group at 6 months, this did not occur in the intestine. It appears that the response by the intestine to conserve sodium is no longer present in resected patients over the 6-month period, whereas this conservation process had persisted in the nonresected patients. There is no doubt that patients with an ileal resection can conserve fluid and sodium from the intestine, but the stimulus to do so apparently must be particularly strong.

3296 MUCOSAL-CELL COUNTS IN ULCERATIVE AND GRANULOMATOUS COLITIS. *(E.)* Sommers, S. C.; Korelitz, B. I. (Lenox Hill Hosp., New York, N.Y.). *Am. J. Clin. Pathol.* 63(3):359-365, 1975.

Epithelial and connective-tissue cells were counted in rectal mucosal biopsies from 215 patients with ulcerative colitis, 98 with granulomatous colitis and 50 controls. Significantly decreased mucous goblet cells were found both in sigmoidoscopically abnormal ulcerative colitis and in granulomatous colitis, and they increased during the healing process. More pyknotic and karyorrhectic epithelial cells occurred in active ulcerative colitis than in granulomatous colitis. Inactive ulcerative colitis still manifested histologic evidence of acute and chronic inflammation, while sigmoidoscopically normal granulomatous colitis biopsies after previous gross rectal disease showed significantly increased macrophages in the lamina propria. Cell counts were valuable for differential diagnosis after the sigmoidoscopic appearance became normal. To identify specific influences of medication, ulcerative colitis groups treated with salicylazosulfapyridine, prednisone, or 6-mercaptopurine were analyzed. Salicyazosulfapyridine therapy was associated with an overall decrease in mucosal leukocytes. Significantly decreased neutrophils were found after prednisone or 6-mercaptupurine, decreases in plasma cells occurred after all three types of therapy, and increased mast cells were found after 6-mercaptopurine. All three combinations of any two of these drugs were associated with significantly decreased plasma cells. Combinations of 6-mercaptopurine with either prednisone or salicylazosulfapyridine was correlated with increased macrophages. Prednisone with salicylazosulfapyridine was associated with significantly increased mast cells. The results of this study support the statement that colonic mucous goblet cells are reduced in active ulcerative colitis. Further, while the leukocytic exudates of these inflammatory intestinal diseases in active states differed only in the more abundant eosinophils in granulomatous colitis, in quiescent states ulcerative colitis and granulomatous colitis connective-tissue-cell populations were distinctive, with persisting exudative inflammation in ulcerative colitis and mobilized macrophages in granulomatous colitis.

3297 RED CELL ABNORMALITIES ASSOCIATED WITH SULPHASALAZINE MAINTENANCE THERAPY FOR ULCERATIVE COLITIS. *(E.)* Pounder, R. E.; Craven, E. R.; Henthorn, J. S.; Bannatyne, J. M. (Cent. Middlesex Hosp., London, England). *Gut* 16(3):181-185, 1975.

Red cell abnormality occurring in patients receiving sulphasalazine was studied to determine the incidence of such changes. Hematological studies were performed on blood samples taken from 50 patients receiving a mean dose of 2.5 g sulphasalazine/day as maintenance therapy for ulcerative colitis, 10 patients with ulcerative colitis not receiving sulphasalazine and 50 controls. Red cell morphology was assessed independently by two observers. Of the treated patients, 35 were found to have one or more drug-induced abnormalities not found in controls or in untreated patients. Contracted red cells were observed in 23 of the treated patients; the abnormality was related to the dose of sulphasalazine, the serum total sulphapyridine level, and acetylator status. Of the treated patients, 11 had a macrocytosis, 21 had elevated levels of methemoglobin, and one had Heinz bodies. A dose of 1.5 g sulphasalazine/day was not associated with red cell contraction, and is suggested as a safer dose for the long-term treatment of the asymptomatic colitis.

3298 THE THYROID IN ULCERATIVE COLITIS AND CROHN'S DISEASE. II. THYROID ENLARGEMENT AND HYPERTHYROIDISM IN ULCERATIVE COLITIS. *(E.)* Jarnerot, G.; Azad Khan, A. K.; Truelove, S. C. (Radcliffe Infirm., Oxford, England). *Acta Med. Scand.* 197(1/2):83-87, 1975.

The incidence of thyroid disease was surveyed in 300 patients with ulcerative colitis and 600 matched controls. The subjects were assessed for simple goiter type thyroid enlargement. A significant increase in frequency of simple goiter was observed in the ulcerative colitis patients (8.7%) compared with 4.3% in the controls. A history of thyrotoxicosis was obtained in 3.7% of the ulcerative colitis patients compared with 0.8% of the controls. In more than half the ulcerative colitis patients with a history of hyperthyroidism, the hyperthyroidism occurred years before the onset of the colitis, suggesting that hyperthyroidism is not likely to be a complication of colitis. Possible explanations for the association of the two diseases are discussed, but it is concluded that no satisfactory explanation has yet been offered.

3299 ULCERATIVE COLITIS. FOLLOW-UP OF 160 PATIENTS OBSERVED FOR AN AVERAGE OF 10 1/2 YEARS. *(Ger.)* Fahrlander, H.; Shalev, E. (Med. Dep., Univ. Basel, Switzerland). *Dtsch. Med. Wochenschr.* 99(43):2141-2147, 1974.

3300 BLEEDING RECTAL POLYPS AS A REASON FOR FALSE POSITIVE DIAGNOSIS OF NONSPECIFIC ULCERATIVE COLITIS IN CHILDREN. *(Rus.)* Kanshina, O. A.; Kanshin, N. N. (A. V. Rusakov Munic. Clin. Hosp. Child., Moscow, USSR). *Sov. Med.* (12):98-102, 1973.

3303 MALABSORPTION OF VITAMIN B_{12} WITH EXOCRINE PANCREATIC INSUFFICIENCY. *(Ger.)* Aenishanslin, H. W.; Stalder, G. A. (Med. Polyclin., Univ. Basel, Switzerland). *Schweiz. Med. Wochenschr.* 104(39):1377-1379, 1974.

Exocrine pancreatic function and vitamin B_{12} absorption, with and without intrinsic factor, were studied in 10 patients, aged 25-64 yr, with histories of chronic pancreatitis dating back 3-120 months. Three patients had malabsorption of vitamin B_{12}, both in the presence and absence of intrinsic factor, while 3 others had malabsorption of the vitamin B_{12}-intrinsic factor complex. Trypsin activities in intestinal juice were significantly decreased in patients with malabsorption of vitamin B_{12} in the presence and absence of intrinsic factor. These findings suggest that vitamin B_{12} malabsorption might have been caused by trypsin deficiency in these patients. In the 3 patients with malabsorption of the vitamin B_{12}-intrinsic factor complex, the findings could be explained if trypsin (1) facilitated binding between intestinal receptors in the ileum and the vitamin B_{12}-intrinsic factor complex and (2) split a hypothetical "binder" which blocks the vitamin B_{12}-intrinsic factor complex. None of the patients with reduced vitamin B_{12} absorption had macrocytic anemia. This is attributed to substitution therapy with trypsin.

3304 EXOCRINE PANCREATIC INSUFFICIENCY IN THE ABSENCE OF CYSTIC FIBROSIS IN INFANTS AND CHILDREN. *(Ger.)* Niessen, K. H.; Osswald, P.; Schmidt, K.; Hartmann, F.; Droste, E.; Brugmann, G. (Pediatr. Clin., Univ. Tubingen, Germany). *Monatschr. Kinderheilk.* 122(7):560-561, 1974.

Pancreatic function was tested in 54 patients, aged 2 months to 16 yr by the secretin-pancreozymin method. Six patients showed reduced enzyme activity, although cystic fibrosis was ruled out by several sweat tests. The cause of pancreatic insufficiency apparently differed in these 6 patients: 3 infants at age 2 months had mucosal atrophy. In one, this probably resulted from celiac disease with secondary pancreatic insufficiency, in another, probably from chronic fibrotic pancreatitis. The third child developed symptoms of pancreatic insufficiency as a result of acute pancreatitis caused by parasite infestation. One child suffered from intermittent neutropenia and increased vulnerability toward infection as in the Shwachman-Diamond syndrome. There was also a case of dwarfism, but no neutropenia or skeletal changes could be detected. Total bile acids in the intestinal juice were reduced in 2 and in the lower normal range in 1 of the patients with pancreatic insufficiency. Bile acid secretion was primarily decreased in the secretin phase. During the secretin-pancreozymin test, patients with total atrophy of the villi secreted significantly larger quantities of bile acids into the intestinal juice than 28 children with normal mucosa or partial atrophy of the villi.

3305 VASOACTIVE INTESTINAL POLYPEPTIDE IN VERNER-MORRISON SYNDROME. *(Ger.)* Seif, F. J.; Sadowski, P.; Heni, F.; Fischer, R.; Bloom, S. R.; Polak, J. M. (Med. Polyclin., Univ. Tubingen, Germany). *Dtsch. Med. Wochenschr.* 100(9):399-405, 1975.

A 40-yr-old man who had been treated for a stomach ulcer 4 yr previously and who had a family history of cancer was hospitalized with intractable diarrhea, hypokalemia, pentagastrin-refractory hypochlorhydria, and reduced pancreatic secretion of bicarbonate, trypsin, chymotrypsin, amylase, and lipase. Radioimmunological studies showed a plasma concentration of vasoactive intestinal polypeptide (VIP) of 800 pg/ml (normal < 100 pg/ml). Plasma concentrations of gastrin-inhibiting polypeptide (GIP), pancreatic glucagon, secretin, and gastrin were all within normal limits. At laparoscopy, multiple metastases were found in the right lobe of the liver, but the type of primary tumor could not be established histologically. Diarrhea did not respond to cytostatic therapy with 5-fluorouracil and cyclophosphamide; symptomatic therapy with tincture of opium, charcoal, pancreatic enzymes, and acid substitution; 0.625 mg pentagastrin s. c. every 3 hr for 3 days; serotonin antagonists and inhibitors of serotonin synthesis (8 mg cyproheptadine 4 times a day, 4 mg methysergid twice a day, 1000 mg DL-*p*-chlorophenylalanine 4 times a day); or prostaglandin synthetase inhibitors (500 mg acetylsalicylic acid 3 times a day, 100 mg indomethacin 3 times a day). Improvement in the diarrhea occurred only with daily infusions of 500 ml of concentrated amino acid solution. Diarrhea ceased and parenteral correction of the water and electrolyte balance became unnecessary 36 hr after administration of 100 mg prednisolone 21-succinate sodium i. v. followed by 10 mg fluocortolone p. o. every 6 hr, but subclinical diabetes mellitus became manifest and was treated with 12 IU depot insulin twice a day. At surgery, a primary non-β-cell islet carcinoma which was strongly positive for VIP was removed from the head of the pancreas; the right lobe of the liver was partially resected; and a cholecystectomy was performed. Lymph node metastases were found at the root of the mesentery and the porta hepatis. Diarrhea did not recur when prednisolone 21-succinate sodium and ACTH were discontinued 1 week after surgery, and plasma VIP concentrations decreased to normal levels. However, the patient developed abdominal abscesses and died of septic cardiovascular failure 68 days after surgery.

3306 POSSIBLE PARATHYROID ORIGIN OF GASTRIN IN A PATIENT WITH MULTIPLE ENDOCRINE ADENOPATHY TYPE I. *(E.)* Cassar, J.; Polak, J. M.; Cooke, W. M. (Hammersmith Hosp., London, England). *Br. J. Surg.* 62(4):313-316, 1975.

A 52-yr-old woman with multiple endocrine adenopathy type I (pituitary, parathyroids, and islet cells) presented with spontaneous hypoglycemia that resolved after removal of two large pancreatic insulinomas, 1 in the tail and the other in the body of the pancreas. Shortly after her discharge the patient was readmitted with severe epitastric pain, hematemesis, and melena. Despite a rise in serum gastrin, there was no evidence of a gastrin-producing tumor. The serum gastrin remained high after truncal vagotomy and pylorplasty were carried out for a bleeding duodenal ulcer and after an antrectomy was performed due to persistent melena. After antrectomy, the basal acid output was 3.1 mEq/hr; peak acid output in response to pentagastrin, 11.3 mEq/hr; and fasting gastrin, 538 pg/ml. The serum gastrin level remained high until hypercalcemia and hyperparathyroidism had been corrected by subtotal parathyroidectomy. In the resected portions of the parathyroid glands, there was diffuse hyperplasia affecting both chief and oxyphil cells. The latter were identified by the presence of numerous mitochondria (mitochondrion-rich cells) and contained electron-dense polymorphic secretory granules predominantly localized toward the vascular poles of the cells. Antiserum against human parathyroid hormone showed reactive chief cells scattered throughout the glands and concentrated around blood vessels. Most of the oxyphil cells were stained positively with an antiserum against human gastrin I. This finding suggests that these cells were the source of the gastrin.

3307 PANCREATIC ABSCESS: A CRITICAL ANALYSIS OF 113 CASES. *(E.)* Camer, S. J.; Tan, E. G. C.; Warren, K. W.; Braasch, J. W. (Lahey Clin. Found., Boston, Mass.). *Am. J. Surg.* 129(4):426-431, 1975.

Records of 113 patients (48 women and 65 men, aged 35-76 yr) with pancreatic abscess were reviewed in an effort to define diagnostic, therapeutic, and prognostic parameters of importance in the management of this disorder. The cases, seen over a 23-yr period, were analyzed in terms of signs, symptoms, and laboratory data, bacteriologic, radiologic, and operative findings, and management. Of the 107 patients who underwent operative drainage, 17.7% died. Complications were varied and often multiple, only 24 patients having and entirely smooth course. Complications included hemorrhage, pulmonary problems, renal and hepatic failure, postoperative fistula, postoperative gastric retention, prolonged ileus, and residual abscess requiring operative drainage. Among 88 survivors, there were 12 known deaths within the first 6 months. Deaths were due to pancreatic carcinoma, duodenal carcinoma, chronic inanition and spesis, adrenal insufficiency, liver failure, and myocardial infarction. Forty-nine patients are alive, 30 of whom have been asymptomatic or have had mild symptoms of no functional significance. Seventeen patients required further operations on the pancreas and biliary system and 19 patients have pain and symptoms of pancreatic insufficiency. Useful diagnostic aids include radiographic examination, selective visceral angiography, and ultrasonic scanning. Successful management involves a timely, aggressive surgical approach, with wide debridement and sump drainage and liberal use of supportive measures such as feeding jejunostomy, gastrostomy, colloid infusion, and enteral and parenteral hyperalimentation.

3308 MORPHOLOGICAL CHANGES IN THE PANCREAS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLERODERMA. *(Rus.)* Skorodumova, N. P. (Donetsk Med. Inst., USSR). *Vrach. Delo* (2):32-36, 1975.

Histological studies were performed on sections from the head, body, and tail of the pancreas, major pancreatic artery, and large pancreatic veins from 204 autopsies of collagen patients, of whom 50 had systemic lupus erythematosus (SLE) and 25 had systemic scleroderma (SS). The pancreas was affected in 20 cases of SLE and in nine cases of SS. Changes were observed in all the structural components of the pancreas (vessels, stroma and parenchyma). The most significant changes were found in the intrapancreatic ramifications of the pancreatic artery in the form of mucoid swelling, fibrinoid changes, cellular reactions and sclerosis. Changes in the veins consisted of either a moderate or marked sclerosis of the walls, edema and small lymphoid infiltrates in the outermost layer. Sclerosis of the walls of the veins prevailed in SS, while edema and cellular infiltration were more characteristic of SLE. The foci of mucoid and fibrinoid swelling were characteristic dystrophic changes of the pancreatic stroma in SLE, while pronounced sclerotic processes in the stroma, the walls of the ducts and perivascular tissue were more characteristic of SS. Atrophic and dystrophic changes were observed in the pancreatic parenchyma. A correlation was observed between the changes in the parenchyma and the vessels. This suggests a possible secondary involvement of the parenchyma in the pathological process.

3320 CHRONIC PANCREATITIS, SCLEROSING CHOLANGITIS, AND SICCA COMPLEX IN TWO SIBLINGS. *(E.)* Waldram, R.; Tsantoulas, D.; Kopelman, H.; Williams, R. (King's Coll. Hosp., London, England). *Lancet* 1(7906):550-552, 1975.

A new syndrome of chronic pancreatitis, sclerosing cholangitis, sicca complex, and other features was found in a brother and sister, aged 36 and 31 yr, resp. The woman's history of difficulties extended over a 5 yr period; the brother had had intermittent epigastric pains from the age of 10. In both, the main features were now those of chronic pancreatitis and sclerosing cholangitis. Additionally, the brother had sialectasis, generalized lymphadenopathy, and moderate leukopenia, while the sister showed the histological and clinical features of sicca complex and eosinophilia. Obstruction of the lower end of the common bile duct, a very rare complication of chronic pancreatitis, was present in both patients. Leucocyte migration was measured in these 2 cases as part of a larger study of cellular immunity in patients with chronic liver disease. In 4 of 5 cases of sclerosing cholangitis, including both of these presently reported cases, migration was significantly inhibited. Leukocytes from their parents and from one of the 2 apparently healthy siblings migrated normally in the presence of the bile antigen. Migration inhibition has not been found in patients with extrahepatic obstruction due to gallstones or pancreatic carcinoma. The bile antigen has been shown to be derived from the bile duct epithelial cells, and the finding of cellular immunity to this material in sclerosing cholangitis suggests that immune mechanisms may be important in the pathogenesis of this disease.

3321 THE AETIOLOGY OF HYPOCALCAEMIA IN ACUTE PANCREATITIS. *(E.)* Condon, J. R.; Ives, D.; Knight, M. J.; Day, J. (St. Mary's Hosp., Eastbourne, England). *Br. J. Surg.* 62(2):115-118, 1975.

The mechanism of hypocalcemia in acute pancreatitis was investigated in 30 patients. Parathyroid hormone was assayed in 11 of 12 hypocalcemic patients and three of 18 normocalcemic patients. Calcitonin was assayed in three of the hypocalcemic patients. Glucagon was assayed in all of the above and in 12 additional normocalcemic patients, 11 of whom had measurements made before and after administration of glucagon (1 mg i.v. followed by 1-1.5 mg 4-hourly i.v. infusion). All measurements were made by radioimmunoassay. Parathyroid hormone was undetectable in the plasma of eight hypocalcemic patients (calcium 7.8 mg/100 ml). One hypocalcemic patient had an elevated parathyroid hormone level of 675 pg/ml. One hypocalcemic and two normocalcemic (9.0-9.9 mg/100 ml) patients had parathyroid hormone levels of 100-175 pg/ml. Three subjects showed serial changes in parathyroid hormone level. One showed a drop from 1.5 ng/ml to 0.5 ng/ml along with a calcium level drop of 8.9 to 8.5 mg/100 ml within 24 hr. A second was normocalcemic with a high parathyroid hormone level that fell gradually. The third was hypocalcemic initially, but both the parathyroid hormone level and calcium level rose; glucagon administration did not result in hypocalcemia in these last two. Calcitonin was not detected in three of the hypocalcemic patients. Mean fasting glucagon levels were 0.48 in 15 normal subjects, and 0.45 in 26 pancreatitis patients. After glucagon infusion, plasma glucagon rose significantly by 3.4-4.0 ng/ml in 1 hr except in two patients. Plasma calcium fell significantly from 0-12 hr, while there was no significant difference in glucagon levels from 1-12 hr. Between 0 and 1 hr, the greater the increase in glucagon concentration, the smaller the fall in plasma calcium. There was no such relationship at 12 hr. It is concluded that persistent hypocalcemia associated with acute pancreatitis is due to a relative deficiency of parathyroid hormone level and is unrelated to glucagon and calcitonin levels.

3322 LIPODYSTROPHY, PANCREATITIS, AND EOSINOPHILIA.

(E.) Smith, P. M.; Morgans, M. E.; Clark, C. G.; Lennard-Jones, J. E.; Gunnlaugsson, O.; Jonasson, T. A. (Univ. Coll. Hosp., London, England). *Gut* 16(3):230-234, 1975.

Two cases are presented of partial lipodystrophy associated with pancreatitis and eosinophilia. In each case the onset of the lipodystrophy was at the age of 5 yr. In one case, recurrent eosinophilia was associated with episodes of recurrent acute pancreatitis. There was also an attack of left renal pain, followed by a temporary impairment of renal function at one point. In the second case there was chronic pancreatitis associated with eosinophilic gastroenteritis. Bilateral non-obstructive hydronephrosis was also diagnosed. Partial lipodystrophy is commonly associated with renal disease, but has never before been associated with pancreatitis. It is suggested that in these cases the eosinophilia was associated with the pancreatitis, but no conclusions are drawn between the interrelationship of the pancreatitis, eosinophilia, and lipodystrophy.

3323 INTENSIVE CARE IN ACUTE PANCREATITIS.

(Ger.) Schonborn, H. (2nd Med. Clin., Univ. Mainz, Germany). *Langenbecks Arch. Chir.* 245-250, 1974.

Of 20 patients who died of acute pancreatitis despite intensive care, all had hemorrhagic necrotizing pancreatitis. Acute renal failure, acute encephalopathy (both of which are irreversible), and shock are indicative of fatal pancreatitis. In patients who survived for less than 12 days, these symptoms manifested themselves within the first 3 days of illness. A pancreatectomy (Child) was performed on 10 patients with total necrosis of the pancreas. Four patients died. Of the 6 that survived, all had normal renal function at the time of operation. It is concluded that severe cases of pancreatitis which might prove fatal should be operated on as soon as possible, and no later than the 6th to 8th day of illness.

3324 ANTINUCLEAR FACTORS IN PATIENTS WITH PANCREATITIS OF UNKNOWN ETIOLOGY. ARE THERE CLEAR INDICATIONS OF AN IMMUNOLOGICAL GENESIS? *(Ger.)*

Neher, M.; Lemmel, E. M. (Surg. Clin., Univ. Mainz, Germany). *Dtsch. Med. Wochenschr.* 100(8):362-367, 1975.

Indirect immunofluorescence was used to determine antinuclear antibodies in sera from 31 patients with pancreatitis. The cause of the pancreatitis (trauma, biliary disease, alcohol abuse) was known in 20 cases and unknown in 11. None of these patients had any other diseases, such as systemic lupus erytheomatosus or liver disease, which are known to be accompanied by the production of antinuclear antibodies. Antinuclear antibodies were present, in most cases in high titers, in 8 of 22 patients with chronic pancreatitis and in 4 of 9 patients with acute pancreatitis. These antinuclear antibodies were shown to consist of IgG and IgM. Of the 11 patients with pancreatitis of unknown etiology, 9 had positive tests for antinuclear antibodies, while only 3 of the 20 with pancreatitis of known etiology had positive tests. With 1 exception, antinuclear antibodies were present in the first sample of serum taken from patients with acute pancreatitis. These findings suggest that some forms of pancreatitis might be autoimmune in nature.

3325 SECRETIN-PANCREOZYMIN TEST. *(Ger.)*

Tympner, F.; Domschke, W.; Koch, H.; Demling, L. (Med. Clin., Univ. Erlangen-Nuremberg, Erlangen, Germany). *Dtsch. Med. Wochenschr.* 99(32):1611-1615, 1974.

After placing a Lagerlof tube in the stomach and duodenum, the secretin-pancreozymin test was performed on 50 normal subjects (29 men and 21 women; mean age 33.2 yr); 34 patients (23 men and 11 women; mean age 38.7 yr) 3-8 weeks after the onset of acute pancreatitis; 48 patients (38 men and 10 women; mean age 41.5 yr) with chronic pancreatitis; 86 patients (51 men and 35 women; mean age 47.3 yr) suspected of having pancreatic disease; and 15 patients (11 male and 4 female; mean age 23.6 yr) with juvenile diabetes. During the entire 2.5 hr, a ^{58}Co-labeled vitamin B_{12} solution (0.7 µCi in 28 ml 0.9% NaCl) was instilled into the duodenum. By measuring the radioactivity of secretion aspirated from the stomach and intestine, 0-12% (mean 4.5%) and 11-97% (mean 49.8%), resp., of the ^{58}Co-labeled vitamin B_{12} was recovered. After i.v. administration of secretin, the enzyme output first increased above the basal value and then decreased. Enzyme output increased during infusion of secretin and pancreozymin and then remained almost constant. In controls, the bicarbonate output ranged from 12.4-43.1 mEq/hr (mean 23.1); the trypsin output, from 85-391 IU/min (mean 183); the chymotrypsin output, from 41-251 U/min (mean 102); the amylase output, from 440-2189 IU/min (mean 982); the lipase output, from 901-4865 IU/min (mean 2093); the protein output, from 0.48-4.76 g/hr (mean 1.51); and the bilirubin output, from 1.89-171.0 mg/hr (mean 18.0). Results of the secretin-pancreozymin test were abnormal in 62% of the patients recovering from acute pancreatitis, in all 48 patients with chronic pancreatitis; and in 10 of the 15 patients (66%) with juvenile diabetes. None of the 68 patients suspected of having pancreatic disease who had normal secretin-pancreozymin tests had pathological findings on endoscopic pancreatography. Of the remaining 33 patients with abnormal secretin-pancreozymin tests, 11 had radiological evidence of chronic pancreatitis; six had papillary stenosis and five, pancreatic cysts at surgery. Four patients had inoperable pancreatic carcinoma, and one young patient had cystic fibrosis which was diagnosed by determining sweat electrolytes.

3326 A BRITISH FAMILY WITH HEREDITARY PANCREATITIS. *(E.)* Sibert, J. R. (R. Victoria Infirm., Newcastle-upon-Tyne, England). *Gut* 16(2): 81-88, 1975.

A British family with hereditary pancreatitis was studied. The disease was definitely diagnosed in 9 members (by clinical signs, a raised serum amylase, or laparotomy, and once by pancreatic calcification seen radiographically) and was suspected in 15 others. The clinical signs included recurrent attacks of epigastric or central abdominal pain, sometimes radiating to the back, often associated with vomiting, and usually lasting 3-4 days. These attacks generally started in childhood or young adult life (mean age of onset in this group was 12.6 yr) and ceased by the age of 40. The pattern of inheritance in this family corresponds well with an autosomal dominant inheritance with incomplete penetrance, which agreed with previously reported families. However, unlike in some previous reports, there was no aminoaciduria in this particular family. It is suggested that hereditary pancreatitis may have been underdiagnosed in Great Britain, and the increased awareness may aid in the differential diagnosis of relapsing pancreatitis, especially in children and young adults.

3327 FRUSEMIDE-INDUCED PANCREATITIS. *(E.)* Jones, P. E.; Oelbaum, M. H. (Manchester North Hosp., London, England). *Br. Med. J.* 1(5950): 133-134, 1975.

A case of acute pancreatitis in which furosemide (frusemide) was implicated as the etiological agent was reported in a 64-yr-old female hospitalized with a myocardial infarction complicated by mild left ventricular failure. After receiving 80 mg/day furosemide for 4 weeks, the patient developed hiccuping, eructations, upper abdominal discomfort, and vomiting. Serum amylase was elevated (80 U/100 ml), as was the serum lipase (3.3 U/ml), and a diagnosis of acute pancreatitis was made. At the end of the seventh week the furosemide was stopped and within 36 hr the abdominal pain, vomiting, and eructation had eased considerably. The serum amylase and lipase began to fall, and a cholecystogram was normal. At the end of the 10th week furosemide was given again in a dose of 40 mg/day and the next day the epigastric pain and eructations returned. The serum amylase and lipase also increased. As before, when the furosemide was discontinued the clinical signs disappeared and the blood values began to return to normal. Thus it is suggested that the diuretic furosemide was responsible for the episodes of acute pancreatitis.

3328 INFLUENCE OF EXOCRINE AND ENDOCRINE PANCREATIC FUNCTION ON INTESTINAL BRUSH BORDER ENZYMATIC ACTIVITIES. *(E.)* Caspary, W. F.; Winckler, K.; Lankisch, P. G.; Creutzfeldt, W. (Dep. Med., Univ. Gottingen, Germany). *Gut* 16(2):89-92, 1975.

Digestive enzymatic activities (disaccaridases, alkaline phosphatase, peptide hydrolases) were studied in small bowel mucosal biopsies from 14 patients with chronic pancreatitis and 10 healthy controls. All chronic pancreatitis patients had abnormal secretin-pancreozymin tests, four had insulin-dependent diabetes mellitus, four had a pathological glucose tolerance test, and nine had steatorrhea. Multiple small bowel biopsies were obtained with a hydraulic biopsy tube under fluorscopic control beyond the ligament of Treitz after an overnight fast. All biopsies showed normal villous structure and light microscopy revealed no signs of mucosal atrophy or inflammation. Maltase, sucrase, and alkaline phosphatase activity was significantly elevated in the chronic pancreatitis patients, whereas lactase, trehalase, and peptide hydrolase activities were normal. Patients with steatorrhea had higher maltase and sucrase activity than those without steatorrhea, while decreased glucose tolerance had no effect on brush border enzymatic activity. It was suggested that decreased exocrine function, rather than decreased endocrine function, was responsible for the increase in intestinal disaccharidase and alkaline phosphatase activity, possibly by the influence of pancreatic enzymes on the turnover of brush border enzymes from the luminal side of the mucosal membrane or by direct hormonal stimulation through cholecystokinin.

3329 CLINICAL AND IMMUNOLOGICAL PARALLELS IN PATIENTS WITH PANCREATITIS AND CHOLECYSTITIS. *(Rus.)* Bordonos, V. G.; Reingardt, B. K.; Maltsev, V. N.; Khramov, A. V. (Kiev Med. Inst., USSR). *Vrach. Delo* (11):74-77, 1974.

Immunological studies were performed on 46 patients with acute and chronic pancreatitis, cholecystopancreatitis, acute cholecystitis and cancer of the pancreas. Autoantibodies to the pancreatic and hepatic tissues were identified by the passive hemagglutination (PHA) and complement fixation (CF) tests. The PHA test was considered positive in titers above 1/8; the CF test varied from weakly positive (+) to strongly positive (+++). The results showed that the highest titer of autoantibodies was observed on the second week after the aggravation of the disease. A correlation was found between the antibody titer and the severity of the disease. The CF test was positive in 22 of the 31 patients; the PHA test in 26 of the 40 patients. A case is reported of a 66-yr-old woman with acute pancreatitis, who on the third day of hospitalization had PHA at 1/32 and CF +++; on the

13th day, PHA 1/512 and CF +++; at the time of the discharge, PHA 1/128, CF +++. Some time later the patient had recurrent pancreatitis. The results indicate that autoantibody tests offer in some cases more reliable criteria to determine the onset of a complete remission. It is suggested that the identification of autoantibodies in the sera of patients with different forms of pancreatitis by PHA and CF tests should be part of clinical examination.

3330 THE EFFECT OF ACTIVE ELASTASE ON THE PANCREATIC TISSUE. *(Rus.)* Chernoiarova, O. D.; Podolskii, A. E. (Sci. Res. Inst. Gastroenterol., Moscow, USSR). *Biull. Eksp. Biol. Med.* 77(11):122-125, 1974.

Histological, histochemical and electron microscope studies of the pancreatic tissue were conducted. Female albino rats weighing 160-180 g were injected with 0.65 or 2.6 mg of elastase into the pancreatic duct; the animals were sacrificed at different intervals. It was found that elastase injection induced acute pancreatitis within 15 min accompanied by the reduction of the amount of proelastase in the tissue and decrease of the inhibitory activity of the serum. One hr after the injection, acute necrotic pancreatitis developed, accompanied by diapedetic hemorrhages into the perivascular space. An increase of the elastase dose to 2.6 mg resulted in the destruction of the elastic membrane of the vein wall. The data obtained suggest an important role played by elastase in the pathogenesis of acute pancreatitis.

LIVER AND BILIARY TRACT

3347 INTRAHEPATIC ARTERIOVENOUS FISTULA RESULTING FROM NEEDLE BIOPSY: A CASE REPORT. *(E.)* Okuda, K.; Kotoda, K.; Igarashi, M.; Karasawa, E. (Chiba Univ. Sch. Med., Japan). *Acta Hepatogastroenterol. (Stuttg.)* 21(6):422-425, 1974.

A case report is presented in which an intrahepatic arteriovenous fistula developed in a 36-yr-old male alcoholic who had undergone needle biopsy approximately one month previously. On admission, coagulation studies were normal although several liver function tests, including total and direct bilirubin (1.7 and 1.0 mg%, resp.) were abnormal. The patient had radiologic evidence of cardioesophageal varices. Percutaneous needle biopsy of the liver was performed without incident. The specimen contained a small portion of parenchyma and a long segment of fibrous portal tract with some vessel wall tissue. Celiac angiography performed 4 weeks later revealed simultaneous opacification of a branch of the right hepatic artery and several portal vein branches. The contrast medium in the portal branches persisted for a few sec after disappearance of the arterial opacification. No bruit was audible over this area. The defect was seen in the same area in which the biopsy had been performed. The patient improved, was discharged after two months and has remained unchanged on follow-up examination. It is concluded that a post-biopsy hepatic arteriovenous fistula should be considered in anyone who manifests increased portal hypertension or from whom a large piece of portal tissue is obtained.

3348 DISCRIMINATIVE AND PROGNOSTIC SIGNS IN ACUTE HEPATIC COMA, TREATED BY EXCHANGE TRANSFUSIONS. *(E.)* Demedts, M.; De Groote, J.; Vandamme, B.; Desmet, V. J. (St. Rafael Acad. Hosp., Louvain, Belgium). *Digestion* 11(1/2):105-114, 1974.

Factors affecting prognosis were evaluated in 14 consecutive cases of hepatic coma. All patients were in coma, apparently due to acute viral hepatitis, for 6-36 hr prior to initiating treatment. This included multiple exchange transfusions with 3-7 liters fresh whole blood, prednisone (25-250 mg/day), correction of electrolyte imbalance, hydration, and other supportive therapy. Clinically, no distinction could be made between the encephalopathy exhibited by the 5 survivors and the 9 who died. Patients whose outcome was ultimately favorable responded with improved consciousness after 2-4 transfusions (3 days) and generally became fully alert within 6 days. Several, however, developed transient complications which included significant ascites (2), bleeding stress ulcers (2), and septicemia (1). Patients who eventually died showed a progressively deteriorating course with no response to transfusion. No patients who presented with severe dysrhythmias on EEG survived. Prior to exchange transfusion, patients who eventually died had higher mean arterial ammonia levels (0.28 mg% *versus* 0.16 mg%) and more prolonged prothrombin times (< 15% of control *versus* 5-50%) than did those who survived. Liver biopsy specimens from patients who died showed more extensive necrosis with interlobular confluence than did those from surviving patients. Biopsies taken up to 7 yr later from patients who survived showed no evidence of cirrhosis. It is thus concluded that assessment of EEG changes, arterial ammonia levels, prothrombin times and liver histology may be of prognostic value in patients with hepatic coma.

3349 BILE ACID KINETICS IN RELATION TO SEX, SERUM LIPIDS, BODY WEIGHTS, AND GALLBLADDER DISEASE IN PATIENTS WITH VARIOUS TYPES OF HYPERLIPOPROTEINEMIA. *(E.)* Hellstrom, K.; Kallner, M. (Serafim Hosp., Stockholm, Sweden). *J. Clin. Invest.* 54(6):1301-1311, 1974.

Fifteen normolipidemic and 61 hyperlipidemic subject/patients (35-67 yr, 23 with various gallbladder diseases and the rest with nongastrointestinal diseases or normal) were maintained on a standardized diet of the natural type for 4-7 days. Caloric intake was adjusted to keep the body weight constant. [^{14}C]Cholic acid (4 μCi) and [^{3}H]chenodeoxycholic acid (15 μCi), as sodium salts were dissolved in water and taken p.o. before breakfast. Four samples of duodenal bile were collected from each at 2-4 day intervals. Cholecystokinin was given i.v. and 5-10 ml concentrated duodenal bile obtained through a thin tube. The specific radioactivities of cholic acid and chenodeoxycholic acid were determined in each sample. Venous blood samples were drawn 4-6 times and analyzed for cholesterol, triglyceride, and lipoprotein pattern. The total bile acid formation was within normal limits in patients with hyperlipoproteinemia types IIa and IIb. The average production of cholic acid represented less than 50% of the total bile acid synthesis in both groups. The corresponding value for the controls was 64%. The synthesis of cholic acid in hyperlipoproteinemia type IIa was significantly below normal. Of the 27 patients with the type IV pattern, 18 had a synthesis of cholic acid and cholic acid + chenodeoxycholic acid that exceeded the upper range recorded for the controls. In these subjects the cholic acid formation represented 73% of the total bile acid synthesis. Similar findings were also encountered in 5 patients with the type V lipoprotein pattern. The bile acid pool size of the 11 patients with hyperlipoproteinemia type IV, who had been cholecystectomized or suffered from cholelithiasis, was 900 mg smaller than that of the other subjects with the same type of hyperlipoproteinemia. The pool size of the former subjects, however, still tended to be higher than that of the controls. In all groups, the formation of bile acids tended to be higher in males than in females. Bile acid synthesis showed no linear correlation to actual body weight, relative body weight, or body surface area. A moderate weight reduction in 5 patients was followed by a 50% reduction of the cholic acid and chenodeoxycholic acid synthesis. It is suggested that the abnormal low density lipoprotein metabolism in hyperlipoproteinemia type II is closely linked to abnormal bile acid kinetics which may or may not be the more fundamental defect. The mechanisms responsible for the accumulation of very low density lipoprotein in hyperlipoproteinemia type IV have not been established. The large bile acid pool size and the tendency to elevated fractional bile acid turnover in this disorder suggest a defect at the intestinal level.

3350 DISPOSABLE ORGAN CHAMBER FOR PERFUSION OF THE EX VIVO LIVER AND ITS USE IN THE TREATMENT OF HEPATIC COMA. *(E.)* Hanson, C.; Baker, P. R.; Cuschieri, A. (Dep. Surg., Univ. Liverpool, England). *Eur. Surg. Res.* 6(1):41-45, 1974.

Two female patients, one 50 yr old and the other 20, in hepatic coma were treated by extracorporeal hepatic assist using a plastic disposable organ chamber for the perfusion of the *ex vivo* liver. The organ chamber consisted of a 12-inch diameter plastic salad container and a 5.5-inch diameter plastic funnel. The liver was held in a 10-inch plastic colender and the entire chamber covered with a clear plastic lid. The entire organ chamber was siliconized prior to sterilization using acid glutaraldehyde. Using this organ chamber, hepatic assist of 3.5 hr duration was performed on the 50-yr-old patient when in stage IV coma. Blood ammonia was 300 μg/100 ml; total serum bilirubin was 4.3 mg/100 ml. A liver from an 18 kg pig was used, the circuit being primed with fresh human blood of the same blood group as the patient's. The estimated blood flow through the liver was low for the first 30 min, but thereafter averaged 300 ml/min. The patient recovered full consciousness within 18 hr of the assist, and her blood ammonia dropped to 64 μg/100 ml. She died of bronchopneumonia 14 days after the assist. The bronchopneumonia was believed not to be due to the porcine liver perfusion because the infection did not develop until 10 days later. It is suggested that the improvement in cardiac and renal function after assist in this patient may be due to removal of toxic metabolites by the porcine liver. The second patient, who was in an advanced degree of cirrhosis, was given hepatic assist for 3 hr eight days after a colonic by-pass operation. The same technique was used as for the first patient. The average liver blood flow during perfusion was 300 ml/min. The patient regained partial consciousness the following day and was fully conscious on the 4th day after the assist. Her blood ammonia decreased from a pre-assist level of 210 to 55 μg/100 ml 48 hr after perfusion. Severe jaundice continued, however, and serum bilirubin went to 30 mg/100 ml. Renal failure developed 12 days after the assist and she died on the 20th day. Although the patients died, the assist was considered successful because the patients regained consciousness shortly after the procedure. According to the authors this disposable organ chamber has several advantages: 1) venous outflow from the perfused liver is unimpeded and can be measured to provide an immediate assessment of the efficiency of the perfusion; 2) the colender provides greater maneuverability of the liver within liver chamber; and 3) connection of the cannulae is a quick and easy process.

3351 ERYTHROCYTOSIS IN HEPATOCELLULAR CARCINOMA: A COMPENSATORY PHENOMENON. *(E.)* Tso, S. C.; Hua, A. S. P. (Dep. Med., Univ. Hong Kong, Queen Mary Hosp.). *Br. J. Haematol.* 28(4):497-503, 1974.

Nine patients with erythrocytosis complicating hepatocellular carcinoma were studied to determine whether erythropoetin or its precursor was autonomously produced by the tumor. At least two plasma samples and three consecutive 24-hr urine samples were collected prior to phlebotomy, and more samples were taken for 3 days after phlebotomy. Plasma was assayed for erythropoetin with hypertransfused plethoric mice and the pH, volume, and creatinine concentration of the urine were determined. For comparison, plasma samples were collected from three polycythemia vera patients before and after phlebotomy. Plasma and urine samples were also collected from two normal subjects and three with gastrointestinal bleeding. Plasma erythropoetin levels rose following phlebotomy in seven patients, in three of which the rise was significant. In contrast, no rise was seen in the polycythemia vera patients. None of the carcinoma patients showed a significant rise in urinary erythropoetin output after phlebotomy. The gastrointestinal patients showed a fluctuating but definite elevation of erythropoetin activity in both plasma and urine. It is suggested that the increased erythropoetin levels and resultant erythrocytosis are compensatory in nature rather than autonomous.

3352 HEMOCHROMATOSIS: PATHOPHYSIOLOGIC AND GENETIC CONSIDERATIONS. *(E.)* Ross, C. E.; Muir, W. A.; Ng, A. B. P.; Graham, Jr., R. C.; Kellermeyer, R. W. (Univ. Hosp. Cleveland, Ohio). *Am. J. Clin. Pathol.* 63(2):179-191, 1975.

Two families with idiopathic hemocromatosis were studied with respect to the mechanisms of pathogenesis and genetics. In addition to routine hematologic studies, erythrocyte incorporation and uptake studies were performed with ^{59}Fe, and biopsies of bone marrow and liver were stained with hematoxylin and eosin, trichrome, and prussian blue. Electron microscopic studies were also done. In one family only the proband and an older sister showed any evidence of hemochromatosis. The sister died at the age of 23 from the disease, and the proband at the age of 16 showed unmistakable pathological changes. Findings in both included normal or slightly altered liver architecture with some portal fibrosis. There was marked deposition of iron in the hepatic cells, but little or none in the Kupffer cells. In the older sister, cirrhosis was evident, and iron was found in the pancreas in moderate amounts, but only trace amounts were found in the spleen. Bone marrow iron was normal or decreased. In the second family, seven members showed evidence of hemochromatosis. The ages of those with high hepatic cell iron ranged from 27 to 52. Findings included mild portal and interlobular fibrosis, concentration of iron in the hepatic cells, and only trace amounts in the Kupffer cells. The autopsies of the four iron overload cases, in contrast, showed high concentrations of iron in the Kupffer cells with smaller amounts in the hepatic cells, and the splenic and marrow iron was equal to or greater than the hepatic iron. These observations support the view that there are two distinct forms of the disease: a severe autosomal recessive form; and a milder autosomal dominant form with a later onset. It is concluded that both types may be due to a similar defect in the reticulo-endothelial system that places an increased burden on the liver parenchyma cells.

3353 WILSON'S DISEASE. CLINICAL AND LABORATORY MANIFESTATIONS IN 40 PATIENTS. *(E.)*

Strickland, C. G. T.; Leu, M.-L. (Nav. Med. Res. Inst., Bethesda, Md.). *Medicine* 54(2):113-138, 1975.

The clinical and laboratory manifestations of Wilson's disease in 40 patients are reviewed. The 16 males had an earlier mean age at onset (12.2 yr) than did the 24 females (22.1 yr). The average age of the 18 patients who died was 19.1 yr. General symptoms and signs included Kayser-Fleischer rings (37), splenomegaly (21), hyperpigmentation of the legs (20), bleeding and easy bruising (17), edema (12), arthralgias (11) and jaundice (11). Four patients had severe liver failure. Commonly seen neurologic manifestations included poor coordination (28), psychological impairment (27), tremor (26), dysarthria (26), abnormal gait (25), rigidity (24), dementia (23), dystonia (23), drooling (22), choreoathetosis (12) and coma (12). All 40 patients had reduced ceruloplasmin (mean = 0.050 Ravin U). Serum copper was reduced (47 μg%) in all and urinary copper was elevated (344 μg/day) in 33 of the 34 patients tested. Pancytopenia was frequently found and was correlated with splenomegaly. Serum uric acid was decreased (2.5 mg%) in 25 of 32 while uric acid clearancewas increased (1.7 ml/min/1.73m^2) in 21 of 24. Creatinine clearance was reduced in 7 of 24 while cadmium clearance was slightly increased in 4 of 21 and phosphate clearance was markedly elevated in 8 of 22. Hyperaminoaciduria occurred in most patients who had recieved less than one yr of penicillamine treatment. Prothrombin time was the most commonly abnormal liver function test, prlonged in 26 of 33. Total serum proteins were reduced (≤ 6 mg%) in 9 of 31. Proteinuria was present in 13 of 38, three of whom also had hematuria. The varied manifestations of Wilson's disease are stressed; because of the genetic heterogeneity, it is cautioned that manifestations in different patients, from different families, and of different races may have minor variations

3354 COAGULATION FACTOR CONCENTRATE IN THE TREATMENT OF THE HAEMORRHAGIC DIATHESIS OF FULMINANT HEPATIC FAILURE. *(E.)*

Gazzard, B. G.; Lewis, M. L.; Ash, G.; Rizza, C. R.; Bidwell, E.; Williams, R. (King's Coll. Hosp., London). *Gut* 15(12):993-998, 1974.

Nine patients in fulminant hepatic failure were studied for their response to prophylactic infusion of a coagulation factor concentrate containing factors IX, X, II and a small amount of VII with or without heparin. All patients had prothrombin time ratios ≥ 2.2 on admission. Of five patients receiving factor concentrate without heparin, three developed fatal hematemesis and melena within 48 hr of initiation of therapy. All five died, four within one week and the last after 14 days. Extensive hepatic necrosis with gastrointestinal hemorrhage was the major necropsy finding in four. Of the four patients treated with coagulation factor concentrate plus heparin, only one had minor gastrointestinal bleeding. One patient survived and three died of respiratory complications. Coagulation and hematologic profiles did not deteriorate as markedly in the group receiving heparin supplemental therapy. In both groups, clotting factor assays showed increased factor II levels, small changes in factor IX and X levels and uniformly low factor V levels. Factor VIII levels dropped rapidly in patients receiving factor therapy without heparin but did not change appreciably in patients receiving heparin. It is thus concluded that factor IX concentrate cannot presently be recommended in the treatment of bleeding diathesis associated with hepatic failure because of its inability to correct factor deficiency and its possible aggravation of intravascular coagulation.

3355 SHORT-CHAIN ORGANIC ACIDEMIA AND REYE'S SYNDROME. *(E.)*

Trauner, D. A.; Nyhan, W. L.; Sweetman, L. (Univ. Calif. San Diego, La Jolla). *Neurology (Minneap.)* 25(3):296-298, 1975.

Short-chain fatty acid levels were determined using gas-liquid chromatography prior to initiation of therapy in seven patients with Reye's syndrome. Blood samples taken within 24-48 hr after the onset of symptoms showed 3-20-fold elevations in propionate, butyrate and isobutyrate compared to control subjects with no known liver disease. No consistent correlation was found between the concentration of any of the short-chain fatty acids and the eventual clinical outcome. These findings are consistent with previous reports showing elevated total free fatty acids in patients with Reye's syndrome and suggest that certain short-chain fatty acids may play a role in the clinical manifestations of the syndrome.

3356 FASTING SERUM BILE ACID LEVELS IN THE PRIMARY HYPERLIPOPROTEINEMIAS.

(E.) Korman, M. G.; Ellefson, R. D.; Hofmann, A. F. (Mayo Grad. Sch. Med., Rochester, Minn.). *Mayo Clin. Proc.* 50 (2):76-78, 1975.

Fasting serum levels of cholic acid conjugates were measured in 126 males and 107 females with various types of hyperlipoproteinemia by radioimmunoassay. Subjects with type IIa hyperlipoproteinemia had significantly lower levels of cholic acid conjugates (0.10 μM) than did 80 healthy controls (0.50 μM). Patients with type IIb, III, IV and V hyperlipoproteinemia had values similar to those of the control group. The abnormally low fasting value of c[illegible] acid conjugates in type IIa patients is considered to reflect decreased secretion of bile acid into the intestine in such patients, who are known to have defective bile acid synthesis rates and decreased bile acid pool sizes.

3357 COMPARISON OF THE EFFECTS OF TOTAL PARENTERAL NUTRITION, CONTINUOUS INTRAGASTRIC FEEDING, AND PORTACAVAL SHUNT ON A PATIENT WITH TYPE I GLYCOGEN STORAGE DISEASE.

(E.) Burr, I. M.; O'Neill, J. A.; Karzon, D. T.; Howard, L. J.; Greene, H. L. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *J. Pediatr.* 85(6):792-795, 1974.

Clinical status, blood chemistry and platelet function were assessed in a 16-yr-old male with type I glycogen storage disease who was treated with parenteral nutrition, continuous intragastric feeding and portacaval shunt. At the time therapy was initiated the patient had marked hepatomegaly, multiple bruises, fasting hypoglycemia, elevated serum lipids, uric acid and lactic acid, a reduced response to glucagon stimulation, decreased glucose-6-phosphatase activity in a liver biopsy specimen, and abnormal platelet function. Treatment by parenteral nutrition for 21 days resulted in transiently decreased liver size, a return of blood chemistry values toward normal, and normalization of ADP-mediated platelet aggregation. Retreatment six weeks later by continuous intragastric feeding again produced marked improvement in the biochemical profile and in platelet function and a decrease in liver size. On the 23rd day of intragastric feeding, the patient underwent an end-to-side portacaval shunt. Although post-operative uric acid levels and platelet function returned to pretreatment values and hypoglycemic symptoms returned with strenuous exercise and fasting beyond 6 hr, the patient experienced no significant bleeding episodes and grew 4 inches in 5 months. These results indicate that continuous nutrition *per se* will revert the anomalies associated with type I glycogen storage disease and are in agreement with those of previous studies.

3358 CHOLESTASIS IN IMMATURE NEWBORN INFANTS: IS PARENTERAL ALIMENTATION RESPONSIBLE?

(E.) Rager, R.; Finegold, M. J. (Bellevue-New York Univ. Med. Cent. N.Y.). *J. Pediatr.* 86(2):264-269, 1975.

The effect of parenteral alimentation on the development of intrahepatic cholestasis was investigated retrospectively in nine of 15 premature infants (≤ 30 week gestation, birth weight 1250 g) who survived at least 5 days. The nine, who were shown at autopsy to have cholestasis, were compared with the remaining six who did not have cholestasis. All 15 babies who also had respiratory distress, hemorrhage or infection, were maintained by total i.v. hyperalimentation (90 cal/kg in 150 mg/day). Only three of the nine cholestatic patients received some oral nutrition during the first 10 days whereas four of the six noncholestatic patients were successfully fed p.o. during the initial week. None of the affected patients was able to sustain oral or nasogastric feeding during the first 17 days. The fact that cholestasis was seen in one patient fed p.o. except for the last 3 days of life and that cholestasis did not develop in one patient maintained for 20 days on hyperalimentation after 10 days of oral feeding suggested no correlation between the hyperalimentation and cholestasis. Increasing survival did not result in progressive liver disease. It is concluded that early fasting rather than parenteral supplementation may contribute to the development of cholestasis in the small premature infant.

3359 ALPHA-1-ANTITRYPSIN IN DUODENAL FLUID AND GALLBLADDER BILE.

(E.) Kyaw-Myint, T. O.; Howell, A. M.; Murphy, G. M.; Anderson, C. M. (Inst. Child Health, Univ. Birmingham, England). *Clin. Chim. Acta* 59(1):51-54, 1975.

α_1-Antitrypsin concentrations were determined by electroimmunoassay in duodenal fluid from 16 patients aged 7 days to 7 yr being investigated for various gastroenterological problems. In addition, gallbladder bile obtained from five patients post mortem and from one patient at laparotomy was investigated. α_1-Antitrypsin (5.6-32.0 mg%) was detected in 20 of 26 fasting and pancreozymin-stimulated duodenal samples from 13 patients. Concentrations were significantly lower in children with liver disease than in those with extrahepatic diseases. All samples had some degree of trypsin inhibitory capacity which did not correlate with the α_1-antitrypsin concentration. α_1-Antitrypsin (8-40 mg%) was also detected in all bile samples except one from a patient with complete extrahepatic obstruction. Thus, unlike its activity in human serum, α_1-antitrypsin makes only a small contribution to the trypsin inhibitory activity of duodenal contents. The results are consistent with a model in which α_1-antitrypsin is delivered from the liver to the small intestine *via* the bile.

3360 HEPATIC DUCTULAR HYPOPLASIA ASSOCIATED WITH CHARACTERISTIC FACIES, VETEBRAL MAL-

FORMATIONS, RETARDED PHYSICAL, MENTAL, AND SEXUAL DEVELOPMENT, AND CARDIAC MURMUR. *(E.)* Alagille, D.; Odievre, M.; Gautier, M.; Dommergues, J. P. (INSERM, Parrot Hosp., Bicetre, France). *J. Pediatr.* 86(1): 63-71, 1975.

The clinical, biologic and histologic features of a group of 15 patients aged 1-21 yr with hepatic ductular hypoplasia and normal extrahepatic bile ducts are presented. These patients were selected from a larger group of 30 with ductular hypoplasia seen over a 18-yr period. The earliest manifestation of the disease, which is equally prevalent in males and females, was persistent cholestasis seen during the first 3 months of life. Moderate elevations in serum bilirubin concentration were associated with intense pruritus and hepatosplenomegaly even in the absence of portal hypertension. Later in the course of the disease, serum lipids and cholesterol rose to extremely high values and alkaline phosphatase increased 3- to 5-fold. Histologically, bile ducts were absent from most portal triads and mild periportal fibrosis was sometimes present. Other characteristics of the syndrome included: 1) characteristic faces with a prominent forehead, deeply set eyes, a straight nose and a small, pointed chin seen in all 15 patients; 2) a harsh midsystolic murmur over the pulmonic area heard in 12; 3) vertebral arch defects demonstrated in eight; 4) growth retardation in eight; 5) mental retardation (IQ = 60-80) in nine; and 6) hypogonadism in six males, five of whom had high circulating plasma testosterone levels. Family histories positive for neonatal cholestasis among siblings were obtained in three cases. Only two patients died, each without liver failure, and follow-up data indicate that this condition carries a better prognosis than do other types of intrahepatic cholestasis.

3361 THE EFFECT OF LIVER DISEASE IN MAN ON THE DISPOSITION OF PHENOBARBITAL. *(E.)* Alvin, J.; McHorse, T.; Hoyumpa, A.; Bush, M. T.; Schenker, S. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *J. Pharmacol. Exp. Ther.* 192(1):224-235, 1975.

The disposition of phenobarbital was studied in eight normal individuals and in nine patients with cirrhosis and eight patients with acute viral hepatitis. Diagnoses were established by appropriate laboratory and pathologic studies. All subjects had normal renal function and were free of alchohol or other drug ingestion for at least 3 weeks. Following a 12-hr fast, ^{14}C-phenobarbital (0.85 mg/kg, 50 μCi) was administered by duodenal intubation. ^{14}C-Labeled phenobarbital and its principal metabolites, *p*-hydroxyphenobarbital (PBOH) and conjugated *p*-hydroxyphenobarbital (PBOC), were identified and quantitated by chromatographic methods in blood and urine for 5 days. Phenobarbital blood half-life in the control group was prolonged to 130 hr ($P < .05$). No PBOH and only traces of PBOC were detected in the blood of either control individuals or patients with liver disease. Urinary excretion of unchanged phenobarbital was an important elimination pathway of the drug in all groups. As a result of this, phenobarbital blood half-life in cirrhosis was only moderately prolonged. Thus, phenobarbital may be a reasonable choice as a sedative in cirrhosis patients.

3362 EARLY DIAGNOSIS OF LIVER METASTASES: AN EVALUATION OF THE INDIVIDUAL DIAGNOSTIC PROCEDURES. *(Ger.)* Sabitzer, H.; Deimer, E.; Hohenberg, G.; Wickenhauser, J. (Radiother. Inst., Univ. Vienna, Austria). *Wien. Klin. Wochenschr.* 86(19): 573-577, 1974.

Different diagnostic procedures in the early diagnosis of liver metastases are evaluated on the basis of 406 cases in which different diagnostic techniques and their combinations were applied, and a step-by-step diagnostic procedure is proposed. Liver function tests and scintigraphic tests are performed first, after which ultrasonic technique is applied in suspect and positive cases. Biopsy is indicated in suspect diffuse hepatic alterations. Laparoscopy and angiography are recommended if nodular alterations are suspected. Angiography is a method of choice especially in the case of hypervascularized tumors. Liver enzyme and scintigraphic tests suggested metastases in 69 cases. Alkaline phosphatase, leucin arylamidase, and γ-glutamyl transpeptidase tests were found to be the most relevant of all enzyme tests for the diagnosis of liver metastases. The enzyme test results were correct in 68.1% of the 69 cases, and wrong in 17.4%. The scintigraphic findings were correct in 62.3% of the 69 cases, and false-positive or negative in 30%. The ultrasonic test results were correct in 71%, and false-positive or negative in 21%. Arteriography, performed in nine patients, gave correctly positive results in three cases, four correctly negative results in four cases, and one false-positive and negative result in one case each. Metastases were ruled out by laparoscopy correctly in six of nine cases, and confirmed in two cases, while metastases were found in one patient with negative laparoscopic findings at a follow-up after 3 months. All findings from all diagnostic tests were consistent in 16 cases.

3363 BILE ACIDS AND BILE ACID SULFATES IN THE SKIN OF PATIENTS WITH CHOLESTASIS AND PRURITUS. *(Ger.)* Stiehl, A. (Med. Clin., Univ. Heidelberg, Germany). *Z. Gastroenterol.* 12(2):121-124, 1974.

Sulfated and nonsulfated bile acids were extracted from the serum, urine, and skin of seven patients with cholestasis and pruritus and of five controls with cholestasis but not pruritus. Bile acids were fractionated on Sephadex LH-20, taurine and glycine conjugates were hydrolyzed enzymatically, and sulfate esters were subjected to solvolysis before quantitative analysis with gas chromatography. No significant difference was found between total serum or urinary bile acids in patients with cholestasis and pruritus and in those with cholestasis alone. However, bile acids were significantly increased in the skin of patients with cholestasis and pruritus. The content of sulfate esters of bile acids was low in the skin of both groups. In patients with cholestasis and pruritus, cholic acid was present in the highest concentration in the serum, while chenodeoxycholic acid was found in the highest concentration in the skin. In two of five controls, urinary bile acid excretion was increased to 150 mg/24 hr. Since both serum and skin bile acid contents were significantly lower than in patients with cholestasis and pruritus, it is suggested that the large amounts of bile acids excreted in the urine of these patients prevented pruritus from developing.

3364 LAPAROSCOPIC FINDINGS IN ERYTHROPOIETIC PROTOPORPHYRIA. *(Ger.)* Solis-Herruzo, J. A.; Perez-Pena, F. (Med. Clin., Univ. Madrid, Spain). *Z. Gastroenterol.* 12(5):335-340, 1974.

A 25-yr-old man was diagnosed as having erythropoietic protoporphyria on the basis of characteristic skin lesions; deposits of PAS-positive, amylase-resistant hyaline material in the perivascular region of the skin; transitory red fluorescence of RBC in the peripheral blood and a bone marrow biopsy; a positive Rimmington and Cripps fluorescence test in the blood; and normal urinary excretion of prophobilinogen, coproporphyrin, and uroporphyrin. At laparoscopy the entire surface of the liver appeared to be uniformly covered with small granules as in nodular cirrhosis. The parenchyma was bluish-gray in color, similar to that in patients with Dubin-Johnson syndrome, but this diagnosis was ruled out by cirrhosis, the distribution of pigment in the liver, and histochemical analysis of the pigment. No green color suggestive of intrahepatic cholestasis was present. Examination of a liver biopsy showed dilatation of the portal fields with fibrous septa and regenerative nodules. Hepatocytic degeneration and necrosis were evident, and many liver cells contained small quantities of bilirubin. Reddish-brown islets of pigment appeared in the intercellular space, hepatocytes, and bile ducts where they formed thrombi. This pigment showed red fluorescence under UV light. Samples of lyophilized liver contained large quantities of protoporphyrin (573 μg/g) along with coproporphyrin (28 μg/g) and other porphyrins (20 μg/g).

3365 SULFATED AND NONSULFATED BILE ACIDS IN URINE, SERUM, AND BILE OF PATIENTS WITH HEPATOBILIARY DISEASES. *(E.)* Makino, I.; Hashimoto, H.; Shinozaki, K.; Yoshino, K.; Nakagava, S. (Hokkaido Univ. Sch. Med., Sapporo, Japan). *Gastroenterology* 68(3):545-553, 1975.

The concentrations of sulfated and nonsulfated bile acids in the serum, urine, and bile were studied in patients with hepatobiliary diseases and normal subjects. Large amounts of bile acid sulfate were found in the urine of the hepatobiliary disease patients. In patients with acute hepatitis, the daily urinary excretion of bile acid was 68.24 μM/day and the percentage of sulfated bile acid was 83.4%. In patients with chronic hepatitis and cirrhosis, a slight increase in urinary bile acid over normal values was observed (2.89 and 5.27 μM/day, resp.) and the percentage of bile acid was 73.9% and 30.4%, resp. In patients with obstructive jaundice, urinary bile acid was moderately increased (32.62 μM/day) and the percentage of sulfated bile acid was 58.3%. In the hepatobiliary disease patients, the levels of both sulfated and nonsulfated bile acids in the serum were elevated over normal levels. The percentage of sulfated bile acid in normal serum was 9%, and it varied from 0-8218% in the pathological sera. Sulfated bile acid was markedly increased in the sera of patients with obstructive jaundice and acute hepatitis, while chronic hepatitis and cirrhosis were associated with a moderate increase. Large amounts of nonsulfated bile acid were found in all bile acids, but sulfated bile acid appeared only in very small amounts (below 0.5%). The findings suggest that the increased bile acid in the serum of patients with hepatobiliary disease might be more easily excreted in the urine as sulfated bile acid. The results provide no indication of a differential diagnostic significance of sulfated bile acid in various hepatobiliary diseases.

3366 LIVER INCLUSIONS IN ERYTHROPOIETIC PROTOPORPHYRIA. *(E.)* Wolff, K.; Wolff-Schreiner, E.; Gschnait, F. (Dep. Dermatol. I, Univ. Vienna, Austria). *Eur. J. Clin. Invest.* 5(1):21-26, 1975.

Liver histology was studied in two patients, a 21-yr-old man and a 36-yr-old woman, with erythropoietic protoporphyria. Both patients had markedly elevated protoporphyrins, considerable fluorescence and photohemolysis of RBC, but no porphyrinuria. Liver biopsy specimans from both patients obtained on two separate occasions each showed moderate fatty changes, portal inflammation and incipient fibrosis, and occasional focal cell necrosis. The cytoplasm of both hepatocytes and Kuppfer cells contained brown pigment granules which were birefingent and highly fluorescent. On electron microscopy, these granules were composed of straight or slightly curved needle or rod-like crystals 0.04-0.5 mμ long and 70-130 Å wide. The crystals were free in the cytoplasm or were ocassionally within autophagosomes of hepatocytes and were within membrane-delimited phagosomes of Kuppfer cells. The specimens from one patient also exhibited non-membrane-bound paracrystalline bodies within the cytoplasm of hepatocytes and occasionally within extracellular spaces. Needle-like granules such as those seen in the livers of both of these patients have not been reported in patients with porphyria cutanea tarda or other hepatic diseases; thus they may be characteristic for protoporphyric liver disease. The paracrystalline bodies seen in the second patient are, on the other hand, identical to the paracrystalline bodies which have been reported in rare individuals with Wilson's disease, porphyria cutanea tarda, and other liver conditions. These bodies may reflect, in a nonspecific way, a disturbance of hepatocyte function.

3367 BIOCHEMICAL FEATURES OF LIVER LESIONS IN PATIENTS WITH COLLAGEN DISEASES. *(Rus.)*

Pankina, V. Kh. (Inst. Rheum., Moscow, USSR). *Klin. Med. (Mosk.)* 52(7):56-60, 1974.

Studies were made of hepatospecific serum enzymes in 110 collagen patients (59 with rheumatism, 25 with lupus erythematosis, 26 with scleroderma and 25 healthy people). The results showed that all the patients had significant changes in the activity of the enzyme specific for liver pathology. In patients with rheumatism, the activities of histidase and urocanase averaged 1.9 and 3 μM, resp. It is indicated that enlargement of the liver was observed in five of the 44 adult patients, while organospecific enzymes were recorded in 22 cases. In 15 children with rheumatism, the activity of histidase and urocanase prior to chemotherapy was 2.8 and 3.2 μM. After the treatment the enzyme activity returned to normal. In the adults, histidase decreased from 1.6 to 1.1 M, while urocanase activity did not change. Histidase and urocanase activity was elevated in 80% of the lupus erythematosis patients to 2.5 and 4.5 μM, resp. Correlation was observed between enzyme activity and severity of the disease. Liver pathology was found in 80% of the scleroderma patients (histidase 3.0 μM; urocanase 2.3 μM). It is concluded that enzyme activity is indicative of liver pathology in collagen patients with no clinical signs. It is suggested that liver pathology may not be the result of the use of chemotherapeutic agents.

3368 METASTATIC CARCINOMATOSIS OF THE LIVER MIMICKING CIRRHOSIS: CASE REPORT AND REVIEW OF THE LITERATURE. *(E.)*

Borja, E. R.; Hori, J. M.; Pugh, R. P. (Cancer Res. Cent., Columbia, Mo.). *Cancer* 35(2):445-449, 1975.

The case of a 46-yr-old woman with breast carcinoma presenting with ascites, jaundice, spider angiomas, and portal hypertension is reported. On hepatic scan, the liver appeared to be almost the same size as the spleen, a finding frequently seen in cirrhosis. A program of treatment with 5-fluorouracil, cyclophosphamide, prednisone, methotrexate, and triiodothyronine was initiated; furosemide was also given for the ascites. The program was of no benefit and the patient died a few days later from uncontrolled esophageal bleeding. Microscopic examination of the liver at autopsy disclosed metastatic, poorly differentiated adenocarcinoma, similar in pattern to that in a breast biopsy sample. Intense stromal fibrosis and intravascular tumor infiltration with compression of the blood vessels, mainly of the portal system, was also seen. In addition, there was microscopic evidence of tumor invasion of the left breast, right axillary nodes, lungs, adrenal glands, and bone marrow. Five other cases resembling cirrhosis due to breast carcinoma are reported in the literature. The clinical pictures in all 6 cases were similar, with uncontrolled esophageal bleeding being the terminal event in each instance. In 5 of the 6 cases, the liver was larger than normal, and the characteristic histologic feature was the intense, diffuse fibrosis of the liver parenchyma. Type IV mammary carcinoma characterized by widespread metastases and a rapidly fatal course was seen in all cases. Although aggressive therapy directed against the malignant process might alter the course of this invariably fatal complication, there seems little indication for aggressive surgical management of the resulting portal hypertension.

3369 LIVER DISEASE IN RHEUMATOID ARTHRITIS AND SJØGREN'S SYNDROME. *(E.)*

Webb, J.; Whaley, K.; MacSween, R. N. M. Nuki, G.; Dick, W. C.; Buchanan, W. W. (R. Infirm., Glasgow, Scotland). *Ann. Rheum. Dis.* 34(1):70-81, 1975.

The frequency of 2 serological markers of hepatic disease, mitochondrial antibody and smooth muscle antibody, and the frequency of abnormal laboratory tests of hepatic function were prospectively evaluated in 216 patients with rheumatoid arthritis, 32 patients with Sjogren's syndrome, 27 patients with the sicca syndrome, and 289 patients with osteoarthrosis or a form of seronegative polyarthropathy. The highest frequencies of raised serum alkaline phosphatase levels and abnormal BSP excretion tests were found in the Sjogren's syndrome, rheumatoid arthritis, and sicca syndrome patients; most of the mitochondrial antibody, salivary duct antibody-, and smooth muscle antibody-positive patients were also within these disease groups. Among the patients with Sjogren's syndrome, rheumatoid arthritis, and the sicca syndrome, the prevalence of raised serum alkaline phosphatase and glutamic oxaloacetic transaminase levels, abnormal BSP excretion tests, hepatomegaly, and splenomegaly was significantly greater in those who were positive for mitochondrial antibody. Patients with smooth muscle antibody had a greater prevalence of abnormalities of all liver function tests, rheumatoid factor, mitochondrial antinuclear, and salivary duct antibodies, and hepatomegaly than those who were smooth muscle antibody-negative. In rheumatoid arthritis, higher serum alkaline phosphatase levels were correlated with higher articular indices, erythrocyte sedimentation rate (ESR), and serum globulin levels. The obverse was true of patients with sicca syndrome, in whom higher serum alkaline phosphatase levels were correlated with higher BSP excretion values. Higher BSP excretion values also correlated with longer disease duration, higher ESR, and higher serum alkaline phosphatase levels in patients with rheumatoid arthritis and Sjogren's syndrome. Screening for smooth muscle antibody and mitochondrial antibody should provide a useful indication of underlying or associated liver disease in rheumatoid arthritis and other collagenoses.

3370 HODGKIN'S DISEASE AND THE LIVER. *(E.)*

Cowan, R.; Trounce, J. R. (Greenwich Hosp. Gastrointest. Unit, London, England). *Guys Hosp. Rep.* 122(384):221-230, 1973.

Two patients who developed jaundice during the course of Hodgkin's disease are described to illustrate some of the difficulties encountered in the diagnosis and managment of this complication. Although the symptoms of liver disease were clear in both patients (2 men, aged 49 yr and 19 yr, resp.) seriously defective blood coagulation in both cases ruled out liver biopsy, laparoscopy, and laparotomy. The indirect methods of assessing liver disease by liver function tests had considerable limitations, largely because of the lack of specificity of such tests. In both patients, the most unequivocal evidence for liver involvement was a raised level of conjugated bilirubin associated with bilirubinuria, which indicated simply that the liver was abnormal. In general, a marked rise in hepatic transaminases indicates that dead or damaged hepatocytes are leaking their intracellular enzymes into the extracellular fluid; a fall in transaminases indicates that dead or damaged hepatocytes are leaking their intracellular enzymes into the extracellular fluid; a fall in transaminases may indicate overwhelming damage to the liver cell mass. Alkaline phosphatse is a useful indicator of early or focal infiltration of the liver and at such time is commonly the only abnormal liver function parameter. BSP and indocyanine green excretion tests may be used in the serial assessment of overall liver function. Isotope scanning of the liver is useful in visualizing discrete intra-hepatic lesions, and many conditions may be detected as focal abnormalities by this technique. Although liver biopsy has the most diagnostic potential of any test discussed, it requires that the patient have adequate clotting factors. With the availability of effective therapeutic agents for Hodgkin's disease, hepatic involvement should be evaluated and its progress followed carefully. Combination chemotherapy is the best form of drug treatment available, but irradiation of the liver also has a place in the treatment of liver involvement by Hodgkin's disease.

3371 REVERSAL OF SEVERE FATTY HEPATIC INFILTRATION AFTER INTESTINAL BYPASS FOR MORBID OBESITY BY CALORIE-FREE AMINO ACID INFUSION. *(E.)*

Heimburger, S. L.; Steiger, E.; Lo Gerfo, P.; Biehl, A. G.; Williams, M. J. (Keesler Air Force Base, Miss.). *Am. J. Surg.* 129:229-235, 1975.

The successful nonoperative treatment of 3 women in whom fatty metamorphosis developed in the liver after jejunoileal bypass for morbid obesity is reported. In 3 of 13 patients who underwent 6-12 in jejunoileal bypass procedures, symptomatic hepatomegaly developed with near total replacement of the hepatocytes by massive fatty infiltration. After undergoing liver scan, liver biopsy, and liver function tests, the patients were started on a peripheral infusion of 4.45% crystalline amino acid solution (2, l/day), which allowed for fat mobilization while preserving body protein stores. At the end of a 14-21 day infusion period, the serum albumin levels increased by 1 g in all 3 patients; decreases in liver volume of 83, 45, and 40% were also observed. During the infusion period, ketonuria was 4+ in all patients, indicating active lipolysis. Weight losses of 17, 19, and 40 lb occurred. All patients showed marked symptomatic improvement, and postinfusion liver biopsy specimens showed a return to near normal architecture. During a subsequent 5-7 month follow-up period, normal liver size was maintained by a high-protein, low-carbohydrate diet. Hepatic fatty infiltration complicating jejunoileal bypass can be massive and may require restoration of gastrointestinal continuity. This fatty infiltration appears to be caused by protein depletion associated with adequate or high carbohydrate intake. In contrast to standard hyperalimentation solutions, the use of calorie-free amino acid solutions reverses the hepatic infiltration by mobilization of fat. This fat mobilization does not occur as readily in the presence of large amounts of glucose.

3372 IRON ABSORPTION IN NORMAL SUBJECTS AND PATIENTS WITH IDIOPATHIC HAEMOCHROMATOSIS: RELATIONSHIP WITH SERUM FERRITIN CONCENTRATION. *(E.)*

Walters, G. O.; Jacobs, A.; Worwood, M.; Trevett, D.; Thomson, W. (Welsh Natl. Sch. Med., Cardiff). *Gut* 16(3):188-192, 1975.

The relationship between iron stores and iron absorption was studied in 52 healthy adults (22 women) and 15 patients (14 men) with primary idiopathic hemochromatosis. Iron absorption was measured by whole body counting using a flat bed scanning technique; measurements were made before, immediately after, and 14 days after consumption of chicken soup containing 2 mg iron and 0.5 μCi (^{59}Fe) ferric citrate. Iron stores were measured by determination of the serum iron concentration. In the normal subjects, there was a significant negative correlation between serum ferritin concentration and iron absorption; there was no correlation between iron absorption and hemoglobin concentration, serum iron concentration, or transferrin saturation. The mean iron absorption in the normal subjects was 12.6%, and that in the hemochromatosis patients was 2.19%. Although there was a significant negative correlation between serum ferritin concentration and iron absorption in the patients, the mean iron absorption (30%) in patients with normal ferritin concentration was significantly higher than the mean absorption in normal subjects with similar ferritin concentrations. Thus, iron absorption in the hemochromatosis patients corresponded to normal levels only when the serum ferritin concentration was significantly elevated above normal values. In the patients, there was a correlation between chelatable iron and serum ferritin concentration, but not between iron absorption and chelatable iron. The ratio of chelatable iron to ferritin was positively correlated with iron absorption. The data confirm the high iron absorption in hemochromatosis patients in relation to their iron load and support the view that this is associated with an imbalance between chelatable iron and ferritin synthesis.

3373 CANCER OF THE BILE DUCTS ASSOCIATED WITH ULCERATIVE COLITIS. *(E.)* Akawari, O. E.; Van Heerden, J. A.; Fould, W. T.; Baggenstoss, A. H. (Mayo Clin., Rochester, Minn.). *Ann. Surg.* 181(3): 303-309, 1975.

Thirteen cases of bile duct cancer associated with ulcerative colitis were reviewed. These cases represented 0.0062% of all autopsy cases at the Mayo Clinic in the period 1935-1973; they represented 1.6% of all autopsy cases of bile duct cancer in the same period. The mean age at onset of ulcerative colitis was 19 years, in each case the onset being marked by severe diarrhea. After initial severe symptoms, most patients developed a pattern of mild-to-moderate disease with exacerbations and remissions. In 10 patients, the ulcerative colitis was managed by various regimens aimed at symptomatic relief and support; proctocolectomy or total colectomy was performed in 3 cases. In one patient, ulcerative colitis was complicated by colonic cancer. The mean age at onset of symptoms of bile duct cancer was 38 yr. Mode of management of the preceeding colitis did not appear to affect the pattern of disease leading to the onset of bile duct cancer which was insidious in all cases. Symptoms included anorexia followed by progressive jaundice. The tumor had spread beyond the bile ducts in 10 patients by the time cancer was diagnosed. The tumors were difficult to identify and often infiltrated the hepatic hilus. Only 1 patient was considered suitable for curative resection; this patient survived for 31.3 months. Histologically, all patients had adenocarcinomas. In no instance was associated cholelithiasis present. The mean survival period was 18.8 months, with hepatic failure, sepsis, shock, and renal shutdown preceeding death. This series of patients combined with the cases reported in the literature suggest that the association between chronic ulcerative colitis and bile duct cancer is more than chance.

3374 FATTY ACID COMPOSITION OF LIVER TRIGLYCERIDES IN VARIOUS STAGES OF FAT DEPOSITION IN THE PARENCHYMA. *(E.)* Singer, P.; Gnauck, G.; Honigmann, G.; Stolz, P.; Schliack, V.; Thoelke, H.; Kettler, L. H.; Buntrock, P. (Clin. Diabetes Assoc. Dis., Berlin, Germany). *Acta Diabetol. Lat.* 11(1):32-42, 1974.

The relation between the fatty acid pattern of triglycerides, and fat droplet size in hepatocytes was investigated. Biopsy specimens were obtained from 30 diabetic inpatients. One part of each specimen was fixed in formalin for histological study, and the remainder was prepared for gas-liquid chromotography. Hepatocytes were classified into four stages according to fat droplet size, by means of an ocular net: normal (no droplets); small droplets (1.7-6.6 μm); medium droplets (7.9-24.0 μm); and large droplets (20.8-50.0 μm). With increasing droplet size a significant increase in palmitic acid (15.0%-28.7%) and oleic acid (19.3%-45.4%) was found. Significant decreases were found in arichidonic and eicosapentanoic acids (3.6%-0.4% and 25.6%-1.6%, resp.). There was also a slight decrease in myristoleic acid. It is concluded that oleic and palmitic acids are predominant in the fat deposited in the liver as well as adipose tissue.

3375 HEPATIC ARTERY LIGATION AND POSTOPERATIVE CHEMOTHERAPY FOR HEPATIC METASTASES: CLINICAL AND PATHOPHYSIOLOGICAL RESULTS. *(E.)* Sparks, F. C.; Mosher, M. B.; Hallauer, W. C.; Silverstein, M. J.; Rangel, D.; Passaro, Jr., E.; Morton, D. L. (Sepulveda VA Hosp., Los Angeles, Calif.). *Cancer* 35(4):1074-1082, 1975.

The effect of a combination of hepatic artery ligation and postoperative chemotherapy on 19 patients with multiple bilateral unresectable metastases, limited to the liver was investigated. In 13 patients the metastases originated from colorectal carcinoma, and in six from other primary cancers. Chemotherapy alone had been tried unsuccessfully in 16 of the patients. In all but one patient the hepatic artery was exposed within the portal triad, doubly ligated, and divided between the gastroduodenal and cystic arteries. In one patient with gastronoma, only the left branch of the hepatic artery was ligated. Cholecystectomy was performed routinely where the gallbladder was present. In four patients, the inferior phrenic arteries were ligated also, and the falciform, round and triangular ligaments were divided. Postoperatively, oxygen was given by mask or nasal catheter to raise the O_2 pressure in the portal blood. Glucagon was given to three patients. Ligation was not performed in several cases when tumor growth was so extensive as to limit the quality and length of survival. In the 10 patients with colorectal carcinoma in whom ligation was performed, 5-fluorouracil therapy was begun immediately after recovery, by the systemic route in nine, and by catheter into the ligated distal hepatic artery in one patient. The six patients with metastases from other sources were given several different drugs. Sixteen patients survived surgery and were followed up for 19 months. Of the patients with colorectal carcinoma metastases, symptoms improved in four for 4, 4, 16, and 33 weeks. One patient, asymptomatic prior to surgery, remained so for 48 weeks postoperatively, and liver scans showed no changes during this time. In three of seven other patients liver scans showed improvement. Liver size decreased in four patients. Six patients died from 12-72 weeks after surgery. Three patients died from preventable complications, including cardiac arrhythmia, liver laceration during paracentesis, and renal failure. Of the six patients with metastases from other sources, symptoms improved in four patients for 16, 20, 40, and 43 weeks. Liver scans showed improvement in three from 20-43 weeks. Liver size decreased in one for 40 weeks. Four died 83, 40, 20, and 8 weeks after surgery. One had leiomyosarcoma and had initially refused chemotherapy. After 20 weeks of improvement, tumor growth resumed and was resistant to chemotherapy. One patient with melanoma did not respond to combination immunotherapy and chemotherapy, and died after 20 weeks. The overall mortality rate was 16%. Mortality was higher in patients with metastases comprising over 30% of liver volume. It is concluded that hepatic artery ligation and postoperative chemotherapy is effective in selected patients.

3376 CLINICAL ASSESSMENT OF LIVER SIZE IN NORMAL CHILDREN. *(E.)* Younoszai, M. K.; Mueller, S. (Coll. Med., Univ. Iowa, Iowa City). *Clin. Pediatr.* 14(4):378-387, 1975.

Clinical evaluation of liver size by percussion and palpation was tested in 105 children from 5 yr 4 months to 12 yr 3 months in age. The children were placed supine with knees flexed at maximum inspiration. The lower edge of the organ was determined by palpation in the mid-clavicular line, and the upper edge of liver dullness was determined by percussion. Both limits were marked by masking tape and the distance between them measured to the nearest mm and recorded as liver span. The distance between the lower edge of the liver and the costal margin in the right mid-clavicular line; and liver height in the mid-sternal line were measured by the same method. After measurements were made by one investigator, the markings were removed and meausrements were made by a second investigator. These were smaller by 0.4 cm in the boys and 0.2 cm in the girls than those of the first investigator. The correlation coefficient between corresponding measurements of the two investigators was statistically significant. When the liver span of each child was plotted against body weight and age, the slopes of the regression lines were significantly different than zero. The correlation coefficient between liver span and body height was statistically significant, increasing from 7 cm at 5 yr to 9 cm at 12 yr. Measurements of liver height in the mid-sternal region gave no consistent results. Measurements of the liver edge below the costal margin were variable. The maximal difference between investigators was 3.3 cm, while the maximal value was 8 cm. The correlation coefficient between the two sets of measurements was not statistically significant. It is concluded that liver span can be reliably measured in children, as in adults, by percussion and palpation.

3377 THE SELECTIVE INHIBITION OF CHENODEOXYCHOLATE SYNTHESIS BY CHOLATE METABOLITES IN MAN. *(E.)* Pomare, E. W.; Low-Beer, T. S. (Bristol R. Infirm., England). *Clin. Sci. Mol. Mrd.* 48(4): 315-321, 1975.

Pool size and rate of bile salt synthesis were studied in four volunteers by radioisotopic methods. Measured amounts of 24-^{14}C-cholate and chenodeoxycholate containing 3-4 μCi radioactivity each, were simultaneously injected i.v. after an overnight fast. Duodenal contents were aspirated after 3, 24, 48, 72 and 96 hr, and bile salt kinetics were calculated by the isotope dilution technique. Bile salts were separated by thin layer chromatography, chenodeoxycholate further separated from deoxycholate, and their specific radioactivities determined by liquid scintillation counter. Relative proportions of the three bile salts were measured by the 3α-hydroxysteroid dehydrogenase enzyme used to assay cholate, and the salicylaldehyde reaction used to assay deoxycholate. Several days after this first study, the subjects were given capsules containing 0.128 mM deoxycholate. Three subjects with chenodeoxycholate rates of 0.25-0.37 mM/day took the capsules twice daily with the meals, while the fourth (synthesis rate: 0.61 mM/day) took three capsules daily. A second study was begun 16, 29, and 32 days after starting the deoxycholate in the first three subjects (15 with gallstones, 13 cholecystectomized, eight with adult celiac disease, and 28 normal). Deoxycholate administration significantly expanded the deoxycholate pool. This was associated with a significant fall in pool size and synthesis rate of chenodeoxycholate with no change in its half-life, but there was no effect on any of these parameters of cholate. There was no consistent change in total bile salt pool, but total primary bile salt synthesis decreased in three of four subjects. There was an inverse relationship between the percentages of deoxycholate and chenodeoxycholate in all four subjects plus three from a previous study, and the 62 fasting subjects not given bile salts. It is concluded that deoxycholate regulates the size of the chenodeoxycholate pool independently of total bile salt pool size.

3378 SERUM α-FETOPROTEIN CHANGES AFTER PARTIAL HEPATECTOMY IN MAN. *(Ger.)* Lamerz, R.; Grunst, J.; Fateh-Moghadam, A.; Schmalhorst, U.; Pichlmaier, H.; Eisenburg, J. (1st Med. Clin., Univ. Munich, Germany). *Klin. Wochenschr.* 53(3):129-133, 1975.

α-Fetoprotein (AFP) was determined by radioimmunoassay on sera from four patients with serologically and histologically confirmed hydatid disease of the liver before and 1-63 days after surgery. Of these patients, two underwent resection of the left lobe; one of the entire right lobe; and one of half the right lobe. A patient who underwent thyroidectomy with the same type of anesthesia served as a control. Before surgery all patients had serum AFP concentrations in the normal range (below 20 ng/ml). However, 1-3 days after surgery AFP concentrations increased to a maximum of 2760 to 5600 ng/ml, i.e. 130-280 times the upper normal limit. Thereafter, the AFP concentration decreased, rapidly at first and then more slowly. In two cases normal values were found 35 and 53 days, resp., after surgery. The control had normal AFP concentrations both before and after surgery. Increases in serum AFP concentrations after partial hepatectomy are attributed to rapid liver cell regeneration.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

3412 MANAGEMENT OF YOUNG INFANTS PRESENTING WITH DIRECT-REACTING HYPERBILIRUBINEMIA. *(E.)* Sass Kortsak, A. (Dep. Pediatr., Univ. Toronto, Canada). *Pediatr. Clin. North Am.* 21(4):777-799, 1974.

Early detection followed by immediate and intensive investigation is essential for the survival of young infants with direct-reacting hyperbilirubinemia, with an aim toward a specific diagnosis of the underlying disease. Failure to arrive at a diagnosis results in having to distinguish between extrahepatic biliary atresia and other extrahepatic bile duct anomalies which are potentially correctable by surgery on the one hand, and intrahepatic disease leading to cholestasis (neonatal hepatitis syndrome) on the other. The degree of biliary obstruction must be determined and, if complete obstruction is found, whether it is sustained with the passage of time. Serum 5'-nucleotidase and bile acid studies are helpful at this point in the diagnosis. Liver function tests and needle biopsy of the liver also help. Patients with strong suspicion of extrahepatic biliary atresia should undergo surgical exploration between 2-3 months of age or earlier, but not before all avenues of investigation that may lead to another specific diagnosis or may exclude the diagnosis of biliary atresia are exhausted. Patients with long-standing severe cholestasis require dietary management and fat-soluble vitamin supplementation in excess of the normal requirements for maintenance. Patients with long-standing intrahepatic cholestasis may benefit from cholestyramine and/or phenobarbital.

3413 UNCONJUGATED HYPERBILIRUBINEMIA: PHYSIOLOGIC EVALUATION AND EXPERIMENTAL APPROACHES TO THERAPY.

(E.) Berk, P. D.; Martin, J. F.; Blaschke, T. F.; Scharschmidt, B. F.; Plotz, P. H. (Natl. Inst. Arthritis Metab. Dig. Dis. Bethesda, Md.). *Ann. Intern. Med.* 82(4):552-570, 1975.

A physiologic approach to the evaluation of patients with unconjugated hyperbilirubinemia was described, along with a case study of a patient with Crigler-Najjar syndrome and a review of established and experimental methods used to reduce the plasma unconjugated bilirubin concentration. Kinetic studies with radiolabeled bilirubin provided for measurement of the rate at which newly synthesized bilirubin entered the plasma and the rate of hepatic bilirubin removal. Quantitation of both of those variables permitted a precise classification of patients with unconjugated hyperbilirubinemia into those with increased bilirubin production, those with decreased hepatic bilirubin clearance (Gilbert's syndrome), and those in which both factors played a role. A rare case of Crigler-Najjar syndrome was described in which bilirubin encephalopathy developed at 18 yr. Various procedures were used in an attempt to reduce the patient's plasma bilirubin concentration by either increasing bilirubin clearance or reducing bilirubin turnover: drug therapy, phototherapy, and phlebotomy. None of those methods were effective in relieving the patient's jaundice but led to further investigations into specific methods of removing bilirubin from the blood. Hemoperfusion experiments in animals gave results that appeared potentially useful for clinical problems. The studies offered new information about the metabolism of bilirubin in type-1 congenital nonhemolytic jaundice, and suggest that the alternate metabolic pathways by which bilirubin is excreted in this syndrome are in some way dependent on the rate of bilirubin production.

3414 INHERITANCE OF THE DUBIN-JOHNSON-SPRINZ SYNDROME.

(E.) Edwards, R. H. (Armed Forces Inst. Pathol., Washington, D.C.). *Gastroenterology* 68(4):734-749, 1975.

To establish the mode of inheritance of the Dubin-Johnson-Sprinz (DJS) syndrome, propositi were ascertained through liver biopsies of jaundiced patients, pedigree information on propositus families obtained through questionnaires, and the presence or absence of the syndrome in relatives determined by liver function tests Conjugated hyperbilirubinemia and elevated BSP levels (higher at 120 min than at 45 min), characteristic of the DJS syndrome, were observed in 17 of 44 tested siblings of 44 DJS patients. Results of these liver function tests on all of 20 parents and 64 children of propositi indicated that they were not affected. Parents of 11 of 39 DJS patients were reportedly consanguineous. The high frequency of parental consanguinity, the incidence of the syndrome among siblings of patients, the lack of involvement of more than 1 generation within each family, and consideration of other reports of familial DJS syndrome suggest the syndrome is inherited only as an autosomal recessive trait. Reports of cases inherited as a dominant trait are probably due to erroneous diagnosis of propositi or their relatives or to pseudodominant inheritance of the recessive trait. Appreciation of this mode of inheritance may be helpful in the differential diagnosis of the constitutional hyperbilirubinemias and in the elucidation of the nature of the hepatic excretory defect in the DJS syndrome and other constitutional hyperbilirubinemias (Gilbert's and Rotor's syndromes).

3415 LIVER ULTRASTRUCTURE IN GILBERT'S SYNDROME.

(E.) McGee, J. O'D; Allan, J. G.; Russell, R. I.; Patrick, R. S. (R. Infirm., Glasgow, Scotland). *Gut* 16(3):220-224, 1975.

Nine young patients with Gilbert's syndrome were studied, 4 of whom had no symptoms in association with the episodes of jaundice, 3 who complained of nausea, tiredness, and headache, and 2 who had abdominal discomfort. Light microscopy of all liver specimens revealed no abnormality. No hemosiderin or visible bile pigment was observed. Lipochrome pigment in centrilobular zones was rarely prominent and was only sometimes seen in liver biopsies from patients with no disorder of bilirubin metabolism. Similarly the electron microscopic examination showed no abnormalities. Pigmented bodies were not observed in excessive numbers and there were none of the degenerative features in plasma membranes, mitochondria, or sinusoidal cells described by other reports. The rough endoplasmic reticulum was not damaged although the amount was apparently reduced in some hepatocytes. In every case agranular endoplasmic reticulum was very prominent and fairly uniform between the individual parenchymal cells. In only 1 case was there any conspicuous dilatation of these vesicular structures, probably due to some delay in fixing the tissues for electron microscopy. There was a 3- to 9-fold increase in agranular endoplasmic reticulum in these cases. This excess agranular endoplasmic reticulum was the only consistent and notable feature of hepatocyte ultrastructure. None of these 9 patients was alcoholic or had been addicted to phenobarbital or other drugs known to cause hypertrophy of agranular endoplasmic reticulum. It is suggested that this ultrastructural feature may be part of Gilbert's syndrome and could have some diagnostic significance in the investigation of doubtful cases of unconjugated hyperbilirubinemia.

3416 THE METABOLISM OF SULFOBROMOPHTHALEIN (BSP) IN DUBIN-JOHNSON DISEASE. *(Sp.)* Gibert-Queralto, J.; Rodes, J.; de Zubizarreta, A.; Bruguera, M. (Fac. Med., Barcelona, Spain). *Fegato* 19(2):481-497, 1973.

Plasma clearance curves for BSP were studied in four patients with Dubin-Johnson syndrome. Each patient received 5 mg/kg of BSP i.v., and BSP concentrations were measured in blood samples taken 8-150 min after injection of the dye. These plasma clearance curves for BSP were very similar in all four patients: a rapid decrease occurred until 30-45 min after injection, after which total plasma BSP concentrations continued to increase slowly until 120-150 min after injection. At 45 min, BSP retention was increased in three patients and normal in one. The percentage of BSP which returned to the circulation between 45 and 120 min after injection ranged from 10.35% to 12.39% in three cases, i.e. total plasma BSP concentrations were increased to almost the same extent. These findings demonstrate that uptake of BSP by the liver is normal in Dubin-Johnson syndrome, but once the point of saturation is reached, serum BSP levels decrease more slowly in patients with Dubin-Johnson syndrome than in normal subjects. It is suggested that these abnormalities are due to impaired excretion of conjugated BSP from the liver into the biliary tract. This was confirmed by measuring free and conjugated BSP fractions in the serum by thin-layer chromatography on silica gel G and elution with a mixture of *n*-butanol, acetic acid, and water (4:1:6) for 24 hr. Plasma clearance curves for BSP obtained from these patients differed from those in extrahepatic obstructive jaundice and hepatic amyloidosis. In the latter two diseases, the increases in plasma BSP concentrations occurred later (75 min after injection) and more slowly than those in Dubin-Johnson syndrome. BSP retention at 45 min was pronounced in extrahepatic obstructive jaundice but not in Dubin-Johnson syndrome or hepatic amyloidosis. It is suggested that plasma clearance curves for BSP might prove useful in the diagnosis of Dubin-Johnson syndrome, providing that hepatic biopsies were taken for confirmation.

3417 COMPARISON OF TREATMENTS FOR CONGENITAL NONOBSTRUCTIVE NONHAEMOLYTIC HYPERBILIRUBINAEMIA. *(E.)* Arrowsmith, W. A.; Payne, R. B.; Littlewood, J. M. (Seacroft Hosp., Leeds, England). *Arch. Dis. Child.* 50(3):197-201, 1975.

Alternatives to phototherapy for treatment of Arias type 1 Crigler-Najjar syndrome were investigated. A 2-yr-old female developed jaundice at 16 hr of age. Total serum bilirubin was 12.4 mg/100 ml, of which 0.6 was conjugated. Phototherapy treatment was begun and continued for 2 yr. During that time, bilirubin levels ranged from 10-28 mg/100 ml, but mental and physical development remained normal. To eliminate the need for 20 hr phototherapy daily, and allow more normal future development, less restrictive methods of therapy were investigated including potassium aspartate (300 mg twice daily), high fat diet (66.9 g fat/day), phenobarbitone (15 mg/day), uridine diphospho(UDP)-glucose (20 mg twice daily), cholestyramine (2 g twice daily), and agar (1g/kg/day). Each treatment was given for three weeks with three week intervals between treatments. Because of variability during the control period of bilirubin concentration (12-20 ng/100 ml) a statistical method to calculate linear regression for bilirubin concentration on time and its correlation coefficient during each treatment and its control period was developed. The probability that there was a significant linear regression with time, and that the regression was significantly different from the change of bilirubin with time in the control period, was calculated. There was a statistically significant fall with time in serum bilirubin concentration during the treatments with aspartic acid, high fat diet, and cholestyramine. During the high fat diet there was an absolute fall of about 4 mg/100 ml with no gradual progressive change. During cholestyramine treatment there was a highly significant rise in the following control period. The significance of the aspartic acid treatment rested on one pair of values. Continuous cholestyramine therapy was started, and bilirubin values were significantly lower (12.3) after 4 months than in the 8 week control period (15.5) despite reduction in phototherapy time. Present levels range from 9.0-14.0 mg/100 ml. It is concluded that cholestyramine is an effective supplement to phototherapy in the treatment of hyperbilirubinemia.

3418 CONSIDERATIONS OF THE PATHOGENESIS OF NEONATAL HEPATITIS, BILIARY ATRESIA AND CHOLEDOCHAL CYST - THE CONCEPT OF INFANTILE OBSTRUCTIVE CHOLANGIOPATHY. *(E.)* Landing, B. H. (Child. Hosp. Los Angeles, Calif.). *Prog. Pediatr. Surg.* 6:113-139, 1974.

3419 JAUNDICE DUE TO NICOTINIC ACID THERAPY. *(E.)* Einstein, N.; Baker, A.; Galper, J.; Wolfe, H. (Tufts-New Engl. Med. Cent., Boston, Mass.). *Am. J. Dig. Dis.* 20(3):282-286, 1975.

3420 HALOTHANE HEPATITIS — A REPORT OF FIVE CASES.

(E.) Paull, A.; Grant, A. K. (Queen Elizabeth Hosp., Woodville, Australia). *Med. J. Aust.* 1(24):954-957, 1974.

Five cases of acute hepatocellular injury following halothane anesthesia are reported. A 63-yr-old man underwent abdominoperineal resection of the rectum for rectal carcinoma under anesthesia which included halothane. After 21 days cystoscopy was performed, under halothane anesthesia. Five days later a transurethral resection of a hypertrophied prostate was performed, again using halothane. A 60-yr-old woman underwent dilatation and curettage for postmenopausal uterine bleeding under halothane anesthesia. Under halothane anesthesia, an intrauterine radioactive source was inserted 13 days later. Five weeks later, again using halothane, abdominal hysterectomy was performed. A 21-yr-old woman was treated for a vulval abscess, under halothane anesthesia. Six weeks later dental extraction was performed again using halothane. A 55-yr-old man, victim of a boating accident, required four operations during the course of one month and halothane was used as an anesthetic agent on all but the first occasion. A 36-yr-old man had a meniscectomy under halothane anesthesia. About 7 weeks later, hemorrhoidectomy was performed, again using halothane. Each of these patients developed hepatocellular jaundice within 5-12 days after the last exposure to halothane. Liver function tests showed: serum bilirubin 5.9-34 mg/100 ml; SGOT, 100-2800 Karmen U; and alkaline phosphatase, 20-35 King-Armstrong U. No patient had exposure to viral hepatitis nor had any received other known hepatotoxic drugs. In the second case the prothrombin time fell markedly in spite of intramuscular vitamin K therapy and the patient died. In the fourth case, the prothrombin time also fell markedly, but improved after i.m. injections of vitamin K_1. Liver biopsy was performed on every patient and showed changes varying from moderately severe hepatitis to submassive necrosis in the patient who died. It is felt that the incidence of halothane hepatitis can be reduced. It is suggested that halothane not be administered to patients who require several operations within a short period of time, or to those who develop unexplained fever, bilirubinuria, abnormal results on liver function tests or jaundice after its use.

3421 LIVER GRANULOMAS CONTAINING COPPER IN VINEYARD SPRAYER'S LUNG. A NEW ETIOLOGY OF HEPATIC GRANULOMATOSIS.

(E.) Pimentel, J. C.; Menezes, A. P. (Dep. Pathol., D. Carlos I Sanit., Lisbon, Portugal). *Am. Rev. Resp. Dis.* 111(2):189-195, 1975.

Three cases of a new type of hepatic granulomatosis which may occur in rural workers who spray vineyards with a solution of copper sulfate neutralized with hydrated lime (Bordeaux Mixture) for the prevention of mildew are presented. The cases reported occurred in 3 male rural workers, aged 52-59 yr. In each case the patients' symptoms seem to have been triggered or aggravated by intercurrent infections. The patients were exposed to Bordeaux Mixture from 3-15 yr. Diagnoses were confirmed at autopsy and by lung biopsy and were based on an occupational history and on the finding of granulomas and fibro-hyaline nodular scars containing inclusions of copper. In each case hepatic changes were found by histology which consisted of proliferation and diffuse swelling of Kupffer cells, sometimes showing a tendency to gather in clusters, and the formation of well-defined histiocytic or sarcoid-type granulomas. These lesions were always found near the portal tracts. In the one case where micronodular cirrhosis co-existed, the granulomas were found in the fibrous strands that limited the nodules of regenerated hepatic tissue. Liver lesions were not accompanied by significant clinical or biochemical abnormalities. Micronodular cirrhosis and fatty liver, present in one patient each, were probably related to alcohol intake and not to vineyard sprayer's disease. The granulomas described in the liver of vineyard sprayers are a new type of hepatic granulomatosis which can occur in patients with a pulmonary disease of inhalatory origin. The identification of copper within the lesions, revealed by histochemical techniques, characterizes the nature of these granulomas. The cases presented here suggest that in all patients in whom pulmonary and hepatic granulomas of unknown cause co-exist, or in whom the diagnosis of sarcoidosis is made by exclusion, the possibility of the existence of a disease caused by the inhalation of pathogenic dusts must be considered. A possible aggressive substance within the lesions must be sought, using the appropriate histochemical techniques.

3422 LIVER PATHOLOGY IN CHRONIC BRUCELLOSIS.

(E.) Boron, P.; Jezyna, C.; Korenkieciwz, I.; Musiatowicz, B. (Bialystok Med. Sch., Poland). *Acta Hepatogastroenterol. (Stuttg.)* 21(4):261-266, 1974.

Functional and morphological estimation of liver pathology was studied in 116 patients (28 women and 88 men, aged 20-68 yr) with chronic brucellosis. The patients were agricultural and veterinary workers with professional exposure from 1-20 yr, in the majority of cases, from 6-14 yr. Examinations showed that in 32% of the cases liver disorders were observed, while hepatomegaly was found in 88%. Mild hyperbilirubinemia (up to 3 mg%) was noted in 20% of the subjects. Elevated SGPT values were observed in about 18% of the patients. Positive sulfobromophthalein tests were noted in 28.5% of those examined. Hypoproteinemia below 6 g% was noted in 12% and hyperproteinemia in 27.2% of the patients. Hypergammaglobulinemia characteristic for observed liver changes was observed in 60%, hypoalbuminemia in 70%, and hyper-α_2-globulinemia in 72%. Only 8 cases (6.9%) of the 116 patients showed inflammatory infiltrations of a focal nature. In the remaining patients, liver changes histologically distinct did not show specificity for brucellosis. Bile stasis was noted in only six cases. Small symptoms of hepatic fibrosis were noted in five cases. In only one patient did the liver biopsy fail to reveal any pathological changes. In the majority of patients the changes were characteristic of hepatitis *reactiva non specifica*. The content of glycogen in liver cells in clinically active chronic brucellosis was distinctly lower than in cases of clinically nonactive chronic brucellosis and in metabrucellosis. No statistically significant correlation was found between the increasing morphological changes of liver biopsy and the behavior of particular immunoserological reactions. These results indicate that liver pathology in the course of chronic brucellosis has the symptoms of morphological changes and functional disorders. Functional disorders observed on the basis of laboratory parameters rather than on the basis of clinical pictures do not show significant correlation to changes of granulomatous type hepatitis. They are correlated, rather, to the changes of non-specific reaction of liver inflammation.

3423 COAGULATION STUDIES AS A PROGNOSTIC INDEX IN ACUTE LIVER FAILURE.

(E.) Dymock, I. W.; Tucker, J. S.; Woolf, I. L.; Poller, L.; Thomson, J. M. (Withington Hosp., Manchester, England). *Br. J. Haematol.* 29(3):385-396, 1975.

A series of coagulation tests was employed to determine the relative importance of the various mechanisms for the production of the coagulation defect in 12 patients (11 women and one man, aged 8-71 yr) with acute liver failure. Clinical diagnoses in these patients included viral hepatitis (six), paracetamol poisoning (three); and halothane toxicity (three). All four patients who presented in Grade IV coma died, as did one of the seven Grade II patients and the one Grade III patient. All who died had clinical evidence of bleeding, usually from the alimentary canal. None of the survivors bled. Excessively prolonged prothrombin time ratios were encountered in all patients who died. The three with the least disturbance of prothrombin ratio recovered. The other seven formed an intermediate group with ratios between 3.0 and 4.8, three of whom recovered, and four died. Results of the cephalin time were substantially similar to those of the prothrombin time test with no clear indication of chances of recovery. In both these tests there was a lack of correlation with fibrinogen degradation product titers (FDP). In no patient was the euglobulin lysis time less than 1 hr. Fibrinolysis was not likely the cause of raised FDP titers present in seven patients. Fibrinogen levels show no correlation with elevation of FDP. A reasonable agreement is noted between factor-VII levels and clot opacity. The speed of thrombin/fibrinogen reaction did not correlate well with lowered levels; there is no consistent relation to the chances of survival or to the degree of coma. Factor-VII determinations were performed in 11 of the patients and appeared to be quantitatively related to the chances of survival. Six with a factor-VII level of 9% or above survived, whereas five with a level of 8% or below died. There was not, however, a close relation between factor-VII levels and the grade of coma. Indeed the grade of coma did not appear as good a guide to the chances of survival as did the factor-VII assay. No apparent relation was noted between the FDP level and survival. There was no correlation between the platelet count and the elevation of FDP titer. In conclusion, this study emphasizes the importance of the synthetic ability of the liver in determining the prognosis in acute liver failure. The ability of the factor-VII assay to assess survival chances in individual patients suggests that the assay is a reasonably accurate guide

3424 HISTOMORPHOLOGY OF THE LIVER IN DAMAGE PRODUCED BY PHENOLISATIN-CONTAINING LAXATIVES (RECURRENT CHRONIC CHOLANGITIS AND HEPATITIS).

(Ger.) Luders, C. J.; Riske, W. E. O.; Henning, H.; Vogel, H. M. (Wenckebach Hosp., Berlin, Germany). *Virchows Arch.* [*Pathol. Anat.*] 365(4):309-325, 1975.

Semiquantitative histological studies were made of needle biopsies of the liver, obtained at laparoscopy, from 36 women with histories of laxative ingestion. Laxatives containing triacetyl- or diacetylphenolisatin (10-30 mg) were given to these patients 12-24 hr (16 cases), 48 hr (eight cases), 72-96 hr (four cases), or 7-14 days (four cases) before biopsies were taken; two patients received 2 doses each of these laxatives. Before finding out about laxative ingestion, 31 of these patients had the following histological diagnoses: chronic aggressive hepatitis (13 cases), combination of chronic aggressive hepatitis and chronic, nonsuppurating, destructive cholangitis (three cases); inactive chronic hepatitis (eight cases); fibrosis resulting from chronic hepatitis (two cases); and inactive cirrhosis (five cases). Acute phenolisatin-induced liver injury should be considered if biopsies show a combination of chronic aggressive hepatitis with acute cholangiolitis, portal edema, and eosinophilic infiltration. Portal bile ductules show proliferation, infiltration, and destructive changes. The absence of introcanalicular cholestasis rules out a diagnosis of mechanical obstruction of the biliary tract. Signs of inactive chronic hepatitis with portal and septal fibrosis and lymphocytic infiltrates in the portal area are suggestive of phenolisatin-induced damage if neutrophilic or eosinophilic granulocytes are found on closer inspection. The presence of larger numbers of proliferating bile ductules provides further evidence on which to base the diagnosis. Within 3-4 days after laxative ingestion, signs of acute cholangitis begin to regress, but chronic hepatitis is still evident after 7-14 days. The unexpected improvement or recovery of patients with histologically confirmed chronic aggressive hepatitis, primary biliary cirrhosis, or a combination of these two conditions is highly suggestive of drug-induced liver damage, particularly of phenolisatin-induced damage.

3425 CHOLESTATIC HEPATITIS AS AN UNUSUAL ALLERGIC REACTION TO CEPHALOTHIN THERAPY.

(Ger.)

Schaefer, U. W.; Hackenberg, K.; Reinwein, D. (Clin., Univ. Essen, Germany). *Munch. Med. Wochenschr.* 117(7):251-252, 1975.

A 29-yr-old man with a history of recurrent infection, probably caused by *Streptococcus*, had repeatedly developed allergic reactions to various penicillins. These allergies were marked by exanthemas, swellings of the joints, and enlargements of the lymph nodes. Cephalothin (8 g/day in i.v. infusions) was administered for 18 days. However, after 7 days, increases occurred in direct serum bilirubin, SGOT, SGPT, alkaline phosphatase, leucine aminopeptidase, and lactate dehydrogenase levels. Hepatitis-associated antigen was detected by the complement-fixation test in a titer of 1:16. Urinary bilirubin and urobilinogen concentrations increased, and the patient developed jaundice, mild hepatomegaly, and bilateral pleural effusions. After 17-18 days of cephalothin therapy, the patient's temperature suddenly increased to 39.6 C and the percentage of eosinophils increased to 11%. After discontinuation of cephalothin, the temperature decreased and all of the other pathological findings disappeared, suggesting that this was an allergy. Since the skin was not involved and hepatic symptoms were the most evident, the symptoms observed differ from those classically found in a drug allergy. Because cephalothin is not hepatotoxic, the cholestatic hepatitis is considered to be an immunological hypersensitivity reaction.

3426 THE HEPATOTOXICITY OF LAXITIVES: ADDITIONAL RESULTS ABOUT INGESTION OF PHENOLISATINS AND BISACODYL. *(Ger.)* Henning, H.; Vogel, H. M.; von Braun, H. H. (Fohrenkamp Clin., Fed. Inst. Employee Insur., Molln (Lauenburg), Germany). *Z. Gastroenterol.* 12(1):15-18, 1974.

Diacetyldiphenolisatin (10-30 mg), triacetyldiphenolisatin (10-30 mg), or bisacodyl (20 mg) was given to 460 patients, all but 45 of whom had chronic liver disease. Two doses were given to 24 of these patients. Acute exacerbations of the liver disease occurred in 24 cases, and no changes in serum enzyme activities were observed in 436. Chronic aggressive hepatitis was present in 14 of the 24 patients who developed phenolisatin-induced exacerbations. The remaining 10 patients had cirrhosis (three cases); chronic persistent hepatitis with and without cholestasis (four cases); chronic hepatitis with and without suspected aggression (two cases); and hepatic scarring with cirrhosis and ascites (one case). Bisacodyl did not cause any exacerbations of liver disease in the 200 patients to whom it was given. These findings suggest that phenolisatin-containing laxatives are responsible for almost 10% of the chronic liver disease in this group of patients. It is recommended that these laxatives be taken off the market in Germany.

3427 CONTROLLED TRIAL OF REPEATED HALOTHANE ANAESTHETICS IN PATIENTS WITH CARCINOMA OF THE UTERINE CERVIX TREATED WITH RADIUM. *(E.)* Trowell, J.; Peto, R.; Smith, A. C. (Radcliffe Infirm., Oxford, England). *Lancet* 1(7911):821-824, 1975.

The role of halothane in the etiology of liver damage was investigated in 39 women undergoing radium therapy for cervical carcinoma. Patients were randomized either to a halothane group exposed to halothane at each anesthetic (18 patients), or to a control group exposed to various other anesthetics using special halothane-free equipment (21). SGPT was measured in each patient the day before each anesthetic. Four patients in the halothane group developed SGPT levels over 100 IU/liter on admission for the third radium treatment (106-1350 IU/liter). Three had already had three previous exposures to halothane. None of the controls developed SGPT levels over 100 IU/liter, and no other function abnormalities were found in either group. It is concluded that liver damage is more common in cervical carcinoma patients after repeated halothane anesthetics than after other various common anesthetics.

3428 CONTROLLED PROSPECTIVE STUDY OF THE EFFECT ON LIVER FUNCTION OF MULTIPLE EXPOSURES TO HALOTHANE. *(E.)* Wright, R.; Chisholm, M.; Lloyd, B.; Edwards, J. C.; Eade, O. E.; Hawksley, M.; Moles, T. M.; Gardner, M. J. (Southamptom Univ. Hosp., England). *Lancet* 1(7911):817-821, 1975.

Liver function in patients repeatedly exposed to halothane was compared with that of controls given other anesthetics. Patients who had been given at least one anesthetic containing halothane within one yr, and presented again for anesthesia were randomly divided into two groups, one to be given halothane, and the other to be given any other anesthetic from halothane free equipment, except methoxyflurane. Premedication was with opiate and an antisialogogue; induction was with sodium thiopentone or alphadolone/alphaxalone and maintenance was with nitrous oxide and oxygen. Patients presenting for anesthesia more than once were elgible for reentry at random. Venous blood was taken immediately before and immediately after administration of anesthetic, and subsequently every 3-5 days for at least 2 weeks. Liver function tests included SGOT, SGPT, lactic dehydrogenase, total protein, albumin, and alkaline phosphatase. In the 160 patients studied, halothane (80 patients) and control groups (80 patients) were comparable regarding clinical features, blood transfusion history, and drug administration. Four in each group had raised preoperative transaminase levels and were excluded from further study. Two of these (both controls) had had repeated halothane anesthetics during the 40 days before the experiment. Of the remaining 76 halothane patients, 15 had abnormally high transaminase levels during the follow-up, compared with four of the 76 controls. Fourteen of the 15 halothane patients, and three of the four controls had less than four previous anesthetics. Raised SGOT levels were also most common in the halothane group that had had less than four previous anesthetics.

In these patients the time between the anesthetics was considerably shorter than in those who had had more than four previously. Six halothane patients had an SGOT peak over twice normal level; this occurred transiently during the second week. One patient had an SGOT level of 440 U and liver biopsy showed necrosis typical of hepatitis. No other biopsies were done. Of 43 halothane patients who had less than four previous anesthetics, 18 had increased SGPT levels compared to five of 28 controls. It is concluded that repeated halothane exposure may significantly raise SGOT levels, possibly because of hepatocytic necrosis.

3429 HEPATOTOXICITY IN PSORIATICS TREATED WITH LARGE DOSES OF METHOTREXATE. *(E.)* Tindall, J. P.; Krueger, R. T.; Callaway, J. L.; Murrell, Jr., T. W. (Duke Univ. Med. Cent., Durham, N.C.). *Cutis* 15(4):512-517, 1975.

Psoriasis patients (27) who had received a total dosage of over 5 g methotrexate were studied to determine hepatotoxicity. Percutaneous biopsy specimens were taken from the liver, stained with hematoxylin and eosin or Masson-trichome, and divided into four grades: 1)mild or no fatty infiltration, nuclear variability, and portal inflammation; 2)moderate to severe degrees of these same three conditions; 3) fibrosis with septum formation; and 4)cirrhosis. BSP was drawn 45 min after injection of a weight related amount. Folate determinations were made on serum separated immediately after blood drawing. Methotrexate was discontinued for at least three weeks prior to evaluation. Of 15 patients with between 5 and 8 g total dosage, eight had mild or no abnormalities, while five had moderate to severe abnormalities, and one had fibrosis. BSP values ranged from 3-8 and folate values ranged from less than 2 to 7. The average age of those with mild or no abnormalities was 37 yr and of those with moderate to severe abnormalities 56 yr. Of seven patients with over 8 g total dosage, two had no or mild abnormalities, one moderate to severe, and four fibrosis. BSP values were from 4-11 and folate 4-9. Four patients with over 5 g total dosage presented with cirrhosis. In these, BSP values were from 20-50. It is concluded that large doses of methotrexate are not always hepatotoxic, that damage may increase with age, and that biopsy is the best method for detecting liver damage.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

3440 INCIDENCE AND NATURE OF CYTOPLASMIC HEPATITIS B ANTIGEN IN HEPATOCYTES. *(E.)* Gerber, M. A.; Hadziyannis, S.; Vernace, S.; Vissoulis, C. (VA Hosp., Bronx, N.Y.). *Lab. Invest.* 32(2):251-256, 1975.

Liver specimens from patients with various forms of hepatitis B antigen (HB Ag) positive or negative liver diseases were examined to determine the incidence and significance of ground-glass hepatocytes. Liver biopsy specimens (177) from 172 patients, and 6 liver necropsy specimens were fixed in formalin and stained with hematoxylin and eosin and Gomori's aldehyde fuchsin. In addition, 10 specimens were stained with orcein, 25 with methyl green-pyronin, and 25 were given the Fuelgen reaction. Direct fluorescent antibody staining for HB Ag was performed on frozen sections from 13 carriers, and on all HB Ag-seropositive patients with chronic hepatitis. Electron microscopy was performed on glutaraldehyde or formaldehyde fixed and osmium tetroxide post-fixed specimens from three carriers and eight HB Ag-seropositive patients with chronic hepatitis. Ground-glass hepatocytes were detected in 32 specimens in varying numbers. Aldehyde-fuchsin-positive ground-glass hepatocytes were found in all 14 HB Ag carriers and 16 of 60 HB Ag-seropositive patients with chronic hepatitis with or without cirrhosis. None were found in 24 patients with HB Ag-seronegative chronic hepatitis, 33 patients with HB Ag-seropositive or negative acute viral hepatitis, five patients with primary biliary cirrhosis, or 14 patients with drug-induced hepatitis with or without cirrhosis. In two HB Ag-seropositive patients, ground-glass hepatocytes were present in non-neoplastic tissue surrounding a hepatocellular carcinoma. Of 16 HB Ag-seropositive patients with chronic hepatitis and ground-glass hepatocytes, 14 had chronic aggressive hepatitis and two had chronic persistent hepatitis. Ground-glass hepatocytes were more numerous in carriers than in chronic hepatitis patients; in eight of 14 carriers over 5% were aldehyde-fuchsin positive, while only three of 16 chronic hepatitis patients were over 5% positive. Cytoplasmic fluorescence was detected in 13 carriers and in six of 11 HB-positive patients with chronic hepatitis, corresponding in percentage and distribution pattern to the aldehyde-fuchsin positive ground-glass hepatocytes. Electron microscopy showed numerous 20-30 nm tubular and circular structures surrounded by dilated endoplasmic reticulum in the hepatocytic cytoplasm of three carriers and one HB Ag-seropositive patient with chronic hepatitis. It is concluded that HB Ag is detectable by light microscopy as Gomori's aldehyde fuchsin-positive ground-glass appearance of hepatocytic cytoplasm.

3441 ULTRASTRUCTURAL STUDY OF CYTOPLASMIC INCLUSIONS IN CASES OF VIRAL HEPATITIS AND HEPATOMAS. *(E.)* Scotto, J.; Homberg, J. C.; Stralin, H.; Caroli, J. (INSERM, St. Antoine Hosp., Paris, France). *Pathol. Eur.* 9(3):211-216, 1974.

Liver biopsies taken from 32 severe cases of viral hepatitis, 2 cases of chronic agressive hepatitis, and 2 cases of hepatoma, all at least 24 hr before death, showed hepatocellular cytoplasmic inclusions. Specimens were examined by electron microscopy after fixation in glutaraldehyde and/or osmium tetroxide, and by light microscopy after staining in hematoxylin and eosin. Cytoplasmic inclusions with generally round or oval shapes, and no limiting membranes were observed in many of the hepatocytes from the cases of hepatitis. The structure of these inclusions was homogeneous, granular and fibrillar in varying ratio, with the granular component frequently dominant. Mallory bodies, which the inclusions resemble, in contrast have more irregular outlines, commonly are serpiginous in form, and are largely fibrillar with longer and broader fibrils (140-165 Å). The fibrils of the inclusions were short and never thicker than 80 Å, and the granules varied from 15-200 Å. Light microscopy showed the inclusions to be faintly gray, rather than brilliantly eosinophilic like Mallory bodies. The number of inclusions varied from cell to cell without apparent relation to the lobule. In the hepatomas, the inclusions were seen in poorly differentiated tumor cells not showing fatty infiltration. It is concluded that these inclusions are not Mallory bodies, and may represent stored viral material.

3442 TOLERANCE TO HEPATITIS B ANTIGEN: A HYPOTHESIS FOR ITS TERMINATION WITH 'IMMUNE-RNA'. *(E.)* Vyas, G. N.; Ibrahim, A. B.; Rao, K. R.; Schmid, R. (Sch. Med., Univ. California, San Francisco). *Life Sci.* 15(2):261-266, 1974.

An hypothesis is postulated based mainly on previously published reports, on the mechanism of acquiring tolerance to hepatitis B surface antigen (HB$_s$Ag) and a possible approach for terminating this tolerance is proposed. Immunologic tolerance to HB$_s$Ag, evidenced by a lack of specific cellular and humoral immune response to HB$_s$Ag, produces a chronic carrier state which serves as an epidemiologic reservoir for the transmission of viral hepatitis type B. In patients with Down's syndrome, uremia, leprosy, renal transplants, chronic active hepatitis, leukemias, and other malignancies, HB$_s$Ag may persist in the plasma for extended periods of time. This persistence is ascribed to genetically determined or acquired impairment of cell-mediated immunity. In apparently healthy carriers the mechanisms of HB$_s$Ag formation and persistence in the plasma are obscure. The observation of neonatal onset of the chronic carrier state suggests that the fetus may acquire immunologic tolerance to HB$_s$Ag as a result of exposure to HB$_s$Ag during a critical period of its intrauterine life. Slow viral infection with lymphocytic choriomeningitis virus in mice provides an analogous model suggesting immunologic tolerance mediated by T-cells. It is proposed that cell-mediated immunity may be transferred to tolerant individuals with "immunoinformational" RNA derived from leukocytes of persons with demonstrable cell-mediated immunity. Adoptive transfer of cell-mediated immunity with the transfer factor has been unsuccessful in an asymptomatic chronic carrier; however, maternal transfer factor has been reported to cause a 95% reduction of HBsAg over a 4-month period in a patient with neonatally acquired hepatitis B infection. The effectiveness of this immunoinformational RNA for transfer of cell-mediated immunity to chronic carriers could be assessed *in vitro* by leukocyte migration inhibition techniques and in HB$_s$Ag-positive chimpanzees *in vivo*. If these *in vitro* and *in vivo* studies should demonstrate the efficacy and safety of the proposed procedure, it is suggested that immunoinformational RNA be tested for terminating the chronic carrier state in man.

3443 DELAYED HYPERSENSITIVITY IN HEPATITIS B: CLINICAL CORRELATES OF IN VITRO PRODUCTION OF MIGRATION INHIBITION FACTOR. *(E.)* Irwin, Jr., G. R.; Hierholzer, Jr., W. J.; Cimis, R.; McCollum, R. W. (Yale Univ. Sch. Med., New Haven, Conn.). *J. Infect. Dis.* 130(6):580-587, 1974.

Delayed hypersensitivity to hepatitis B surface antigen (HB$_s$Ag) in patients with disease from the clinical spectrum of hepatitis and in controls was examined by an indirect assay of macrophage migration inhibitory factor (MIF). Patients with HB$_s$Ag-positive acute hepatitis and HB$_s$Ag-positive or -negative persistent hepatitis produced MIF. MIF activity was not detected in patients who were receiving steroids or in pregnant patients with acute HB$_s$Ag-positive hepatitis. Patients with a documented history of HB$_s$Ag-positive mild hepatitis (6 months to 2 yr previous) but without continuing clinical or laboratory evidence of liver disease did not demonstrate MIF. Patients with acute hepatitis epidemiologically related to ingestion of shellfish and without a history of drug use or exposure to blood products did not produce MIF. Individuals with antibody to HB$_s$Ag detectable by hemagglutination and/or precipitation in agar gel did not make MIF, nor did antibody-negative normal controls. In one individual, mistakenly given a unit of HB$_s$Ag-positive blood, MIF was not detectable on 2 occasions before the appearance of clinical illness. During and shortly after clinical illness, MIF was present; it was undetectable again 72 days after disappearance of abnormal liver function and clinical signs and symptoms. Results from all categories of patients were reproducible; however, in some cases the degree of inhibition in the second test was lower than in the original test. Thus the ability to detect MIF seemed dependent on the presence of clinical illness at the time of the assay.

3444 NEONATAL HEPATITIS TYPE B--A THREE YEAR FOLLOW-UP. *(E.)* Dahlquist, E.; Nordenfelt, E. (Dep. Infect. Dis., Univ. Lund, Sweden). *Scand. J. Infect. Dis.* 6(4):305-308, 1974.

Counterelectrophoresis and immunodiffusion techniques were used to detect hepatitis B antigen (HB Ag) in 2 cases of newborn children of mothers with hepatitis during pregnancy. The first case was a 31-yr-old woman who developed acute hepatitis during the eighth month of pregnancy. HB Ag subtype *y* was detected in her serum. About a month later she gave birth to a premature but normal female infant. HB Ag subtype *y* was not detected in the infant's serum until about 2 months later. A liver biopsy at 2.5 yr disclosed chronic persistent hepatitis, but she has had normal development and good general condition. The second case was a 40-yr-old woman who developed acute hepatitis in the seventh month of pregnancy. HB Ag subtype *y* was again found in the serum. She gave birth to a normal male infant who became positive for the antigen 33 days after delivery. A liver biopsy about 10 months later disclosed chronic hepatitis, but a second biopsy a month later showed no sign of disease. Although long term effects of neonatal hepatitis are unknown, prognosis appears to be good.

3445 THE EPIDEMIOLOGICAL IMPORTANCE OF 'ay' AND 'ad' SUBTYPES OF THE HB-Ag. *(E.)* Pons-Romero, F.; Heathcote, J.; Sherlock, S. (R. Free Hosp., London, England). *Gut* 15(9):733-736, 1974.

The distribution of the subtypes *ay* and *ad* was assessed in 159 hepatitis B antigen (HB Ag) positive subjects with a variety of associated hepatic conditions. Sixty-nine patients were diagnosed as having acute hepatitis, 17 were healthy carriers, 41 had chronic aggressive hepatitis, 27 had chronic persistent hepatitis, and 5 had primary liver cell cancer. The subjects fell into 1 of 4 geographical groups: 71 came from northern Europe, 57 from Mediterranean countries, 8 from the Middle East, and the remaining 16 from a variety of countries not in these regions. All serum samples were set up against *y* and *d* antisera and tested by counterimmunoelectrophoresis. All of the HB Ag-positive samples could be subtyped either *ay* or *ad*. When the subtyping results from all 159 subjects were considered, there was no significant dishomogeneity between *ay*:*ad* proportions in the various diagnostic groups. However, when compared according to geographic regions, the ratio *ay* to *ad* was significantly greater in the Mediterranean subjects. Differences in the distribution of the two subtypes were also seen within each diagnostic group when its members from northern Europe and the Mediterranean areas were compared. Among the patients with acute hepatitis, this difference in distribution of the two subtypes did not emerge until the patients were separated as to where they were thought to have contracted hepatitis. In nine households where intra-household, non-parenteral transmission of the HB Ag was suspected, the subtype was the same within each household; five were all *ay* and four were all *ad* in type. These results demonstrate that both subtypes may be associated with all forms of HB Ag-positive acute and chronic liver disease and present in healthy carriers. However, the geographical origin of the HB Ag-positive person, and possibly the route of infection with the HB Ag, may influence the subtype findings in any one area. It is suggested that subtype *ay* predominates in

Mediterranean areas while *ad* predominates in northern Europe. It is suggested therefore that infection with a particular subtype of the hepatitis B virus is associated with epidemiological factors and cannot be related to any particular form of hepatic pathology.

3446 HYBRIDISATION OF DANE PARTICLE DNA WITH THE FREE PLASMA DNA OF HEPATITIS CARRIERS.

(E.) Hung, P. P.; Mao, J. C. H.; Ling, C. M.; Overby, L. R. (Dep. Virol., Abbott Lab., North Chicago, Ill.). *Nature* 253(5492):571-572, 1975.

Plasma from commercial donors were screened for Hepatitis B surface antigen (HB$_s$Ag) by radioimmunoassay. Positive specimens were then screened for free DNA by dialysis of 50 ml plasma against Tris buffer containing .01% diethylpyrocarbonate. Cesium chloride was added to the dialyzed plasma to an average density of 1.05 and the solution was centrifuged for 67 hr at 3500 rpm. Synthesis and isolation of ^{3}H-thymidine from Dane particles was also carried out, and this labeled DNA was hybridized with the free DNA isolated from the plasma. Both DNA samples were denatured separately with NaOH, neutralized with HCl, and incubated together in 1 x SSC for 4 hr at 68 C. Unhybridized DNA was digested, and calf thumus DNA was added as a carrier. Radioactivity was determined by scintillation spectrometer. The free isolated DNA possessed homology with the labeled Dane particle DNA, but not with samples of DNA from human liver, WI-38 cells, salmon sperm, or calf thymus. Of 21 HB$_s$Ag-positive plasma samples, all had detectable free DNA of which five randomly selected samples were hybridizable with Dane particle DNA. In contrast, 19 of 21 HB$_s$Ag-negative samples had no detectable free DNA. The remaining 2 had free DNA hybridizable with Dane particle DNA. The length of the free plasma was estimated at 2-3 μm, longer than that of the Dane particle genome, equivalent to a molecular weight of 4 x 10^6 to 5 x 10^6. The results suggest the possibility of using molecular hybridization with immunological techniques to determine potential blood plasma infectivity.

3447 HEPATITIS B ANTIGEN AND ANTIBODY IN MATERNAL BLOOD, CORD BLOOD, AND AMNIOTIC FLUID.

(E.) Papaevangelou, G.; Kremastinou, T.; Prevedourakis, C.; Kaskarelis, D. (Dep. Hyg. Epidemiol., Univ. Athens, Greece). *Arch. Dis. Child.* 49(12):936-939, 1974.

Transmission of hepatitis B virus from carrier mothers to their newborns was studied using hepatitis B antigen (HB Ag) and antibody (HB Ab) in maternal blood, umbilical cord blood, and amniotic fluid. A random sample of 428 women had maternal and umbilical cord bloods drawn. Sixty-nine also had amniotic fluid drawn at delivery and concentrated 10 times. HB Ag was detected by counter-immunoelectrophoresis. Passive hemagglutination assay was used to screen for HB Ab in 173 mothers. HB Ag was not detected in the umbilical cord blood of the antigen-negative mothers, but was shown to be in the umbilical cord blood of two of the 14 newborns of permanent antigen carrier mothers. The antigen was not in blood samples drawn 3 months after delivery of the infants from the carrier mothers, or from the two infants who had positive cord blood. HB Ab was absent in the umbilical blood of one of 38 HB Ab-positive mothers, and was not found in maternal or umbilical blood or amniotic fluid of any of the HB Ag-positive cases. HB Ab was also absent from the amniotic fluid of 59 negative mothers and three of 10 positive mothers. HB Ab titers were significantly lower in amniotic fluid than in maternal or umbilical blood. There was not correlation between HB Ab titers of umbilical blood and amniotic fluid. It is concluded that transplacental transmission from carriers is not uncommon, occurs through exposure of the fetus to the virions, and that antibody to the hepatitis b virus easily crosses the placental barrier.

3448 THE SIGNIFICANCE OF INVOLVEMENT OF THE INTRAHEPATIC BILE DUCTS IN THE GENESIS OF JAUNDICE AND CHOLESTASIS IN VIRAL HEPATITIS.

(Ger.) Bluger, A. F.; Kartasova, O. J.; Maksimova, L. A. (Med. Inst., Riga, USSR). *Dtsch. Z. Verdau. Stoffwechselkr.* 34(1):9-16, 1974.

Clinical symptoms and the findings from liver biopsies were compared in 260 patients with acute viral hepatitis: 70 had the anicteric form and 190 were jaundiced. Signs of cholestasis (pruritus and increased serum alkaline phosphatase, cholesterol, β-lipoprotein, and copper levels) were present in 43 of the 90 patients with jaundice. Changes in intrahepatic bile ducts were detected in 73% of all patients, including 87% of those with jaundice and in 37% of those with anicteric hepatitis. These changes consisted of epithelial abnormalities (cytoplasmic swelling and granulation, nuclear pyknosis, and karyolysis) and desquamation of epithelial cells into the intrahepatic bile ducts; a pronounced mesenchymal reaction; inclusions of neutral lipids and glycoproteins in the cytoplasm of bile duct cells; an increased alkaline phosphatase activity in the walls of the bile ducts; and cytochrome oxidase activity in periductal cell infiltrates. Under the electron microscope, shrinking of the nuclei, vacuolization of bile duct cells, and many fragments of desquamated cells in the lumen were evident. These forms of cholangitis are characterized as (1) catarrhal, (2) obstructive, or (3) destructive. Only catarrhal cholangitis was present in 93% of those with cholestatic hepatitis. The high incidence of obstructive cholangitis in these patients suggests that bile duct lesions interfere with normal production of bile and prevent bile flow in hepatitis. Obstructive cholangitis was also found in 67% of all jaundiced patients, but destructive cholangitis occurred in only one patient with cholestasis. Mathematical analysis of the relation between bile duct lesions and the increase in bilirubin levels showed a close correlation between intact bile ducts or catarrhal cholangitis and bilirubin levels of 5 mg/100 ml or less and a direct correlation between obstructive cholangitis and bilirubin levels of 5 to 10 mg/100 ml or over 10 mg/100 ml. Obstructive cholangitis occurred in 55% of patients with cytolysis syndrome (increased SGOT and iron levels and abnormal thymol turbidity tests). Cytolysis was not related to bile duct lesions, but cholestasis, either alone or accompanied by cytolysis syndrome was correlated with obstructive cholangitis.

3449 SUBTYPES OF HEPATITIS B ANTIGEN AMONG PATIENTS AND SYMPTOMLESS CARRIERS. *(E.)*

Green, H. T.; Turner, G. C. (Fazakerley Hosp., Liverpool, England). *J. Hyg. (Camb.)* 74(1):123-132, 1974.

The relationship between the forms of hepatitis B infection and the *ad*, *ay* and *a* subtypes associated with them were studied in 255 subjects. Of these, 127 had chronic liver disease or were symptomless hepatitis B antigen (HB Ag) carriers, two were infants of HB Ag-positive mothers who became positive at about 2 months of age, and one was an adult with transient antigenemia but no evidence of hepatitis. HB Ag-positive sera were identified by immunoelectrophoresis and subtyped by immunodiffusion using hepatitis B antibody positive sera that gave spurs characteristics of partial identity reactions between preciptin lines with reference to *ad* and *ay* HB Ag-positive sera. The 127 acute hepatitis patients fell into four categories: blood transfusion; illegal drug injections or social intercourse with addicts; miscellaneous parenteral exposure; and contact with HB Ag-positive patients undergoing hemodialysis. Subtypes were found with equal frequency in those with no parenteral exposure and those with blood transfusions, but subtype *ay* was predominant in those with illegal drug injections (100%), social contact with addicts (91%), and such miscellaneous parenteral exposure as tattooing, injections, or accident in medical or dental practice (80%). All hemodialysis cases were *ay* but were all from the same hemodialysis unit. Of 34 post-transfusion cases, 2 groups received their transfusions in Liverpool and North Wales and had subtype *ad* in 64% and 60%, resp. A third group received blood elsewhere, and 70% of them had subtype *ay*. The chronic hepatitis patients fell into 3 categories: symptomless carriers of HB Ag; patients with chronic liver or other diseases; and patients with chronic renal failure on hemodialysis. Of the symptomless carriers, 78% were *ad*, 21% *ay* and 1% *a*. The patients with chronic liver diseases were 55% *ad* and 45% *ay*, and those with non-liver diseases were 71% *ad* and 29% *ay*. All the hemodialysis patients were subtype *ay* but all were in 1 hemodialysis unit. The results confirm previous reports that subtype *ad* is associated largely with chronic or symptomless infection, while subtype *ay* is associated with acute hepatitis.

3450 CONTENT OF TOTAL SERUM HEXOSES BOUND WITH PROTEINS AND THEIR URINARY EXCRETION IN PATIENTS WITH VIRAL HEPATITIS (BOTKIN'S DISEASE).

(Rus.) Fedianin, Iu. P.; Rabinovich, P. D.; Vaistukh, S. I. (Chita Med. Inst., USSR). *Ter. Arkh.* 46(4):63-67, 1974.

The total content of serum hexoses and their urinary excretion was investigated in 67 patients with acute viral hepatitis. The total serum content was 186.0 mg% at the height of the disease; 168.0 mg% after the disappearance of jaundice; and 184.0 mg% during convalescence. The urinary excretion of hexoses in the patients at the height of the disease was nearly twice that of the healthy people (1.066 mg/day and 548.2 mg/day, resp.). During convalescence, the urinary excretion of hexoses was lower (734.0 mg/day) than it was at the height of the disease, but exceeded that of the healthy subjects. The findings also indicate that urinary excretion of hexoses bound with biopolymers and their concentration in the urine of patients was more than 1.5 times higher at the height of the disease than in the healthy people (84.3 mg and 15.7 mg%; 49.5 mg and 9.1 mg%, resp.). During the convalescent period these indices returned to normal (62.8 mg and 10.6 mg%). It is suggested that in patients with acute viral hepatitis, the concentration of serum hexoses bound with proteins increases, while their urinary excretion rises at all stages of the disease. During the convalescent period, the enzyme hexose content and their urinary excretion remain elevated, while the indices of metabolic pigment and proteins return to normal. The total content of hexoses bound with the proteins may be indicative of the severity of the destructive changes in the acute stage of the disease and of the degree of the regenerative processes in the liver during convalescence.

3451 DETECTION AND PATHOGENIC ROLE OF CIRCULATING IMMUNE COMPLEXES INVOLVING HEPATITIS B SURFACE ANTIGEN.

(E.) Trepo, V. C.; Prince, A. M. (New York Blood Cent., N.Y.). *Z. Gastroenterol.* 13: 278-281, 1975.

The role of circulating immune complexes involving the hepatitis B surface antigen (HB$_s$Ag) in the pathogenesis of liver and kidney disease was investigated. Such circulating complexes have been demonstrated in patients positive for HB$_s$Ag or anti-HB$_s$. SGPT levels were compared in 60 asymptomatic chronic HB$_s$Ag carriers with coexisting anti-HB$_s$ and 60 HB$_s$Ag carriers without detectable anti-HB$_s$. The SGPT values did not differ significantly between the two groups, and assessment of hepatic damage by liver biopsy in 70 HB$_s$Ag carriers confirmed the lack of correlation between anti HB$_s$ and evidence of liver disease. When 300 ml of high titer anti-HB$_s$-containing plasma from a hyperimmune chimpanzee was infused into a healthy chronic HB$_s$Ag carrier animal, there was no significant rise in the animal's SGPT values. Thus, circulating HB$_s$Ag/Ab complexes are probably not particularly pathogenic for the liver, although they presumably are involved in the pathogenesis of various extrahepatic manifestations which may be associated with HB$_s$ antigenemia (e.g., vasculitis, polyarthritis, glomerulonephritis). The previously observed dissociation between usually mild anicteric hepatitis and severe lesions of vasculitis and/or glomerulonephritis in patients with periarteritis nodosa or glomerulonephritis associated with persisting HB$_s$ antigenemia suggest that the hepatic and extrahepatic lesions of hepatitis B are probably mediated by two different immunopathogenic mechanisms; circulating HB_sAg complexes are probably only responsible for the latter.

3452 CLINICO-PATHOLOGICAL STUDIES OF THE LIVER IN ASYMPTOMATIC CARRIERS OF AUSTRALIA ANTIGEN (HBAg).

(E.) Ichida, F.; Sasaki, H.; Sekine, T.; Inagaki, T.; (Sch. Med., Niigata Univ., Japan). *Acta Hepatogastroenterol. (Stuttg.)* 22(1):13-21, 1975.

Blood donors (55 males, 1 female) who were carriers of the Australia antigen (HB_sAg) and had normal SGPT values were examined clinically, immunologically, and histologically. Among these subjects, the SGPT was abnormal in 14.5% of the cases, the SGOT was abnormal in 9%, the serum bilirubins were abnormal in 12.2%, the serum alkaline phosphatase level was abnormal in 24.5%, the tolbutamide tolerance test in 4.4%, the ZTT was abnormal in 2.2%, the γ-globulin was abnormal in 21.2%, and the indocyanine green retention was abnormal in 25.6%. Anti-HB_s was negative in all subjects and the rate of lymphocytic blastogenesis in the peripheral blood was low in seven of 19 patients. The migration inhibitory factor test determined by the addition of purified HB_sAg revealed that 17 subjects, excluding one with a histologic picture of acute hepatitis, were not susceptible to HB_sAg. Histologic examinations of liver biopsies in 20 subjects showed nonspecific reactions in seven, acute viral hepatitis in one, and fatty liver in two. Acute viral hepatitis accompanied by very slight inflammatory reactions in the lobules was found in eight subjects, and pleomorphism was noted in the hepatocytes of eight. It is probable that the low humoral and cell-mediated antibody titers to HB_sAg in asymptomatic carriers of HB_sAg are involved in the mechanism of continuous HB_sAg positivity.

3453 HEPATITIS B: A NEW VACCINE READY FOR HUMAN TESTING.

(E.) Maugh, II, T. H. (no affil.). *Science* 188(4184):137-138, 1975.

Viral antigens isolated from human carriers of hepatitis B have been used to prepare a vaccine against this disease. Available evidence indicated that the nucleic acid core of the presumed hepatitis virus replicates in the nucleus of liver cells and migrates to the cytoplasm, where it is sheathed in the protein coat of the hepatitis B surface antigen (HB_sAG or Australian antigen). Early work showed that injections of blood serum from chronic human carriers of HB_sAg protected 70% of a group of children who were later exposed to hepatitis. The new vaccine was prepared by separation of the antigen from viral particles in the blood by centrifugation, purification of the antigen by centrifugation or a chemical procedure, and treatment of the antigen with formalin to inactivate any remaining virus particles. Of four chimpanzees given the vaccine, all developed antibodies to HB_sAg and none developed hepatitis; one animal given a vaccine which had not been exposed to formalin did develop hepatitis. Six months later, all animals were given an infectious dose of hepatitis B virus subtype *ayw*. None of the animals given vaccine prepared from subtype *ayw* developed hepatitis. Although one animal given vaccine prepared from subtype *adr* did become infected, it developed none of the signs of the disease. The next step will be limited testing in humans to ensure that the vaccine is safe. If it is found safe and effective in humans, it can be used to protect individuals who are likely to come into contact with the hepatitis virus.

3454 ACUTE VIRAL HEPATITIS: FACTORS POSSIBLY PREDICTING CHRONIC LIVER DISEASE.

(E.) Dietrichson, O.; Juhl, E.; Christoffersen, P.; Elling, P.; Faber, V.; Iversen, K.; Nielsen, J. O.; Petersen, P.; Poulsen, H. (Kommunehosp., Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 83(1):183-188, 1975.

Clinical, biochemical, immunological, and morphological variables recorded at first hospital admission were compared in 74 patients with uncomplicated acute viral hepatitis and in 28 patients who subsequently developed chronic liver disease. Clinically, the only difference between the two groups was a higher percentage of drug addicts in the group with subsequent chronic liver disease. Although there were some biochemical differences between the two groups, only the highest registered bilirubin values showed a significant difference; they were highest in the group with subsequent morphological normalization. The group that subsequently developed chronic liver disease had significantly higher maximal γ-globulin values, a significantly higher incidence of antinuclear antibodies and smooth muscle antibodies, a significantly higher incidence of Australia antigen subtype Y, and a nonsignificantly higher incidence of Australia antigens of all subtypes. The group which subsequently developed chronic liver disease also showed a higher incidence of defect limiting plate, piecemeal necrosis, and pronounced plasma cell infiltration in the portal tracts on biopsy. The results suggest that the immunological and more detailed morphological changes which distinguish the two groups at the start of acute viral hepatitis are, to some extent, the same as those which are of importance in predicting the prognosis of chronic hepatitis.

3455 HEPATITIS B VIRUS ANTIGEN QUANTITATION BY RADIOIMMUNOASSAY (RIA) IN VIRAL HEPATITIS AND IN CHRONIC LIVER DISEASE.

(E.) De Ritis, F.; Gravina, E.; Squame, G. (2nd Med. Sch., Univ. Naples, Italy). *Acta Hepatogastroenterol. (Stuttg.)* 22(1): 4-13, 1975.

Immunological techniques and a solid-phase radioimmunoassay were used to study the incidence of the hepatitis B viral antigen (HB Ag) in 70 patients with viral hepatitis, 13 patients with chronic active hepatitis, and 20 patients with cirrhosis. As demonstrated by radioimmunoassay, 90% of the patients with posttransfusion hepatitis, 88% of those with acute viral hepatitis, and 35% of those with cirrhosis were positive for HB Ag. In each group, agar gel diffusion, counter immunoelectrophoresis, and complement fixation tests showed a lower percentage of HB Ag-positive cases. The degree of antigenemia was determined using a linear plot of the percent of $[^{125}I]$ HB Ag count bound *versus* increasing dilutions of HB Ag-positive controls. The resulting dose-response curves were used to follow-up 15 patients suffering from acute hepatitis. In the first week, circulating levels of HB Ag were distributed into three classes of values; this distinction was less evident in the following weeks. The concentrations of HB Ag became progressively lower with time, reaching nondetectable levels by the eighth week. Radioimmunoquantitation of HB Ag in the sera of patients with chronic active hepatitis showed a wide range of antigenemia (17-5100 ng/Eq/ml *ad*) in 13 patients. Use of a dose-response standard curve also improved the sensitivity of the radioimmunoassay technique in patients with cirrhosis. The results indicate that radioimmunoassay is more sensitive than other immunological methods for the detection of HB Ag in acute and chronic hepatitis.

3456 IS THERE A RISK OF TRANSMITTING HEPATITIS BY GASTRODUODENOSCOPY? *(Ger.)* Massarat, S.; Urban, M.; Schiff, W. (Med. Polyclin., Univ. Marburg/Lahn, Germany). *Dtsch. Med. Wochenschr.* 100(2): 42-45, 1975.

The risk of transmitting virus-B hepatitis by gastroduodenoscopy was studied in 211 patients who underwent gastroduodenoscopy by using the same endoscope for all patients. After use, the endoscope was sterilized by a routine method, including washing with tap water, immersion in a disinfectant solution for 20-30 min, and final cleaning with 70% alcohol. Five patients had been carriers of Australia antigen (HB_s Ag) before gastroduodenoscopy. The follow-up examinations carried out 2 and 4 months after gastroduodenoscopy revealed HB_sAg in the same five patients, and in two additional patients who, however, had been subjected to this examination before the HB_sAg carriers. One of the two new HB_sAg-positive patients had liver cirrhosis; multiple infusions of albumin had been carried out in the other after gastroscopy. In this case, infusion may have been the cause of HB_sAg transsion. No proven case of hepatitis transmission occurred in this group of patients. The findings indicate low probability of hepatitis transmission at gastroduodenoscopy, and no need for preliminary HB_s Ag tests prior to gastroscopy.

3457 SUBACUTE NECROTIZING HEPATITIS: DIAGNOSIS, COURSE, AND PROGNOSIS. *(Ger.)* Lammli, J.; Vetter, D.; Knoblauch, M.; Schmid, M. (Waid Munic. Hosp., Zurich, Switzerland). *Helv. Med. Acta.* 37(5/6); 403, 1974.

The pathogenesis, symptomatology, therapy, and prognosis of subacute necrotizing hepatitis in 18 female and 4 male patients are described. Serious and protracted jaundice, prolonged impairment of the general health status with asthenia, nausea, and anorexia were the principal symptoms of the disease. Hepatomegaly and splenomegaly were detected in 2/3 and in 1/3 of all cases, resp. Portosystemic encephalopathy, ascites, and edema were frequent, and the bilirubin levels reached an average maximum of 21 mg% in 4.5 weeks. The γ-globulin levels sometimes reached values commonly observed in chronic aggressive hepatitis. Almost 50% of all patients were Australia antigen-positive. The causative agent was determined to be oxyphenisatin-base laxatives in two cases. Organ-unspecific antibodies without prognostic significance were temporarily present in 1/3 of all patients. Three patients died in hepatic coma after 5 weeks. Follow-up examinations after 18 months revealed full recovery in five cases, scarred liver in five, chronic aggressive hepatitis in four, and chronic persistent hepatitis in three cases. Corticosteroid therapy was successful in 13 patients.

LIVER AND BILIARY TRACT

Chronic Hepatitis

3485 IMMUNOGLOBULINS, GLYCOPROTEIDS [SIC!] AND AUSTRALIA ANTIGEN IN CHRONIC LIVER DISEASE. *(E.)* Feher, J.; Jakab, L.; Szilvasi, I. (Semmelweis Univ. Med. Sch., Budapest, Hungary). *Acta Med. Acad. Sci. Hung.* 30(3):197-203, 1973.

The sera of 91 patients with chronic liver disease (16 chronic persistent hepatitis, 25 chronic aggressive hepatitis, 30 cirrhosis of the liver, and 20 fatty infiltration) were studied by radial diffusion to estimate the amount of IgG, IgA, and IgM immunoglobulins, and ceruloplasmin, α_2-macroglobulin, β_1-C-globulin and transferrin. Microcomplement fixation was used to demonstrate the presence of Australia antigen (HB_SAg) and antibody. The titers of humoral antibodies against allogenic hepatocellular nuclei, mitochondria, and soluble protein were estimated by passive hemagglutination. Pooled serum from 100 blood donors served as the control. IgA and IgM levels showed a significant increase in chronic persistent hepatitis compared to the controls as did the levels of all 3 immunoglobulins in chronic aggressive hepatitis and in cirrhosis of the liver. The increase in IgG was particularly marked in chronic aggressive hepatitis. The serum ceruloplasmin and α_2-macroglobulin levels were increased in relation to the extent of the inflammatory process involving the hepatic stroma. In contrast, β_1-C-globulin and transferrin were not significantly affected. HB_SAg and humoral antibodies were seen most frequently in chronic aggressive hepatitis. These results suggest the existence of a definite relationship between the persistence of HB_SAg and the production of chronic parenchymal injury in the liver. They also support the claim that the immune system is affected by chronic hepatitis.

3486 REMISSION OF ACTIVE CHRONIC HEPATITIS AFTER TREATMENT WITH CYCLOPHOSPHAMIDE AND PREDNISOLONE. REPORT OF FOUR CASES. *(E.)* Pengelly, C. D. R.; Jennings, R. C. (Gen. Hosp., Altrincham, Cheshire, England). *Practitioner* 214(1280):233-242, 1975.

Four case reports are presented in which four patients with chronic active hepatitis experienced remission following therapy with prednisolone and cyclophosphamide. The patients, aged 42-74 yr, presented with malaise, dyspepsia, abdominal tenderness and jaundice. All had elevated serum globulins and raised serum aminotransferase levels, and some evidence of disturbed autoimmune mechanisms. Liver biopsy revealed focal necrosis, fibrous bands and plasma cell infiltration. Treatment with cyclophosphamide (25-100 mg/day) and prednisolone (10-20 mg/day) resulted in total remission of disease in three patients with normalization of liver function tests and histology which has persisted for 20-58 months. The fourth patient has progressively improved over a 5 month period. Except for a transcient mild thrombocytopenia in two patients, there were no significant side effects of therapy. It is concluded that combined cyclophosphamide-prednisolone therapy is satisfactory for the treatment of chronic active hepatitis and is probably superior to other modes of therapy because of its ability to suppress autoimmune mechanisms.

3487 INFLUENCE OF AZATHIOPRINE ON HEPATIC RESERVE IN CHRONIC ACTIVE LIVER DISEASE. *(E.)* Rikkers, L.; Sherlock, S. (R. Free Hosp., London, England). *Gut* 16(3):214-219, 1975.

An investigation was conducted to determine if hepatic indocyanine green (ICG) excretion in patients with chronic active liver disease follows saturation kinetics, allowing calculation of the maximal rate of ICG removal (R_{max}), and to assess the role of azathioprine in the management of patients by evaluating the influence of this drug on R_{max}. Following the initial ICG analysis, azathioprine (75 mg/day) was administered to 14 patients (eight men and six women, aged 13-69 yr) with chronic active liver disease. Prednisolone therapy was continued in five patients (10 mg/day). Two weeks later a second ICG study was performed in 11 patients. The hepatic removal in individual ICG doses was exponential in most cases, with the correlation coefficient of the plasma disappearance rate plot exceeding 0.995 in 66 of 82 dose studies (81%). The general conformity of the data to Michaelis-Menten kinetics was confirmed. Initial values for R_{max} and K_m for all patients were 0.47 mg/kg/min and 6.54 mg/kg resp. R_{max} was significantly higher in untreated patients than for those on maintenance corticosteroids. Following 2 weeks of treatment with azathioprine, no improvement was detected in R_{max} in previously untreated patients, those on maintenance prednisolone, or both groups combined. Thus it appears that at least over the short term, azathioprine has no beneficial influence on the liver's reserve for ICG removal in these patients; in fact, in isolated cases this drug may be detrimental. The results of the study indicate that hepatic removal of incremental doses of ICG is consistent with Michaelis-Menten kinetics in most patients with chronic active liver disease, thus providing a means of estimating a maximal removal fate for this dye.

3488 STUDY OF ANTIBODIES FOR ANTILYMPHOCYTE, Au/SH, AND LIVER TISSUE ANTIGENS IN CHRONIC LIVER DISEASE. *(Hun.)* Dobias, G.; Szecsey, G.; Hollos, I.; Barnabas, L.; Kendrey, G. (Dep. Exp. Lab. Anal., Inst Postgrad. Phys., Budapest, Hungary). *Orv. Hetil.* 115(19):1093-1097, 1974.

Lymphocyte cytotoxins, as well as Au/SH and liver tissue antigen antibodies were studied in patients with chronic aggressive hepatitis, chronic persistent hepatitis, and cirrhotic hepatitis. Lymphocyte cytotoxins reacting with allogenic lymphocytes at 15 C were found in serum samples from 30 out of 50 patients. Antibodies reacting with autologous lymphocytes at 15 C were found in 6 out of 50 patients, including two each with chronic aggressive hepatitis, chronic persistent hepatitis, and cirrhotic hepatitis. Lymphocyte cytotoxins reacting with autologous lymphocytes at 37 C were detected in four patients (one case of chronic aggressive hepatitis, two cases of chronic persistent hepatitis, and one case of cirrhotic hepatitis) with below-normal lymphocyte counts, including three cases of leukopenia. Antibodies reacting with untreated Au/SH antigen were found in 14 out of 132 cases, while antibodies reacting with Tween-80-treated Au/SH antigen were found in 38 cases. The incidence of antibodies reacting with liver tissue antigens (MF, SF) was highest in sera from patients with chronic aggressive hepatitis. A significant relationship was established between the presence of Au/SH antigen and liver tissue antigen antibodies in all types of liver diseases studied. Antigen-antibody complexes and several antibodies with different degrees of specificity were found simultaneously in chronic aggressive hepatitis.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

3501 LIVER BLOOD FLOW IN ALCOHOLIC CIRRHOSIS. *(Fr.)* Huet, P. M.; Marleau, D.; Lavoie, P.; Viallet, A. (St. Luc Hosp., Montreal, Canada). *Union Med. Can.* 103(12):2069-2077, 1974.

The severity of portal hypertension in cirrhosis is best evaluated by measuring the portal-hepatic gradient. This gradient ranged from 7 to 26 mm Hg in 54 patients with alcoholic cirrhosis. The portal-hepatic gradient was greater than 12 mm Hg in all patients who had bleeding esophageal varices diagnosed at emergency endoscopy. The varices were 3-4 mm in diameter or larger in all patients with bleeding varices. These results suggest that cirrhotics with portal-hepatic gradients greater than 12 mm Hg are potential bleeders. A portal-hepatic gradient less than 12 mm Hg and small varices suggest that varices are not the cause of upper gastrointestinal bleeding in patients with alcoholic cirrhosis. After combined catheterization of subhepatic umbilical and portal veins and the upper mesenteric artery, ^{51}Cr-labeled RBC were injected into the upper mesenteric artery and dilution curves were obtained for 18 cirrhotics with severe portal hypertension. The portal fraction of total liver blood flow ranged from 30 to 100% (mean 67.3%). There was no correlation between the portal fraction of total liver blood flow and indocyanine green (ICG) clearance, the portal-hepatic gradient, or total liver blood flow. These results suggest that this technique could be used to select candidates for shunt surgery after a critical value for portal blood flow has been established. By using the same catheterization technique, it was demonstrated that ^{125}I-labeled albumin microaggregate uptake ranged from 5.2 to 100% (mean 48.8%) and ICG uptake from 3.9 to 54.0% (mean 22.4%) in 10 patients with cirrhosis. In contrast, normal values were measured in 4 patients with idiopathic portal hypertension. A highly significant correlation between ^{125}I-labeled albumin microaggregate and ICG uptake was found in these 14 patients, as was a highly significant correlation between ^{125}I-labeled albumin aggregate uptake and relative ICG clearance. This suggests that the decrease in these substances is secondary to changes in hepatic microcirculation. The decrease in ^{125}I-labeled albumin uptake which occurs during cirrhosis might result from the fact that some portal blood does not perfuse Kupffer cells because of portohepatic shunts. Thus, ^{125}I-labeled albumin microaggregate uptake might also be used to estimate functional portal flow in cirrhotics.

3502 IDENTIFICATION OF ACTIN-LIKE PROTEINS IN ALCOHOLIC HYALINE BY IMMUNOFLUORESCENCE. *(E.)* Nenci, I. (Inst. Pathol. Anat, Univ. Ferrara, Italy). *Lab. Invest.* 32(2):257-260, 1975.

Alcoholic liver disease Mallory bodies were tested for the presence of actin by means of antiactin antibodies. Liver biopsies were taken from 5 chronic alcoholic liver disease patients and 3 control nonalcoholic patients. Sera of patients with chronic aggressive hepatitis were tested for antiactin antibodies by indirect immunofluorescence. None of the sera contained antimitochondrial, antinuclear, or antireticulin autoantibodies. Cryostat sections of the liver specimens were treated with a 1:50 dilution of the antiactin antibody serum and reacted with fluorescein isothiocyanate conjugated goat anti-human immunoglobulin antiserum. Readings were made by immunofluorescence microscope. Control specimens were treated either with antiactin antibody serum as above, innoculated with normal human sera lacking smooth muscle autoantibodies, or incubated with goat anti-human immunoglobulin antiserum after application of the antiactin antibody sera. All of the antiactin antibody-containing sera stained the Mallory bodies by indirect immunofluorescence. The fluorescent appearance was consistent with the light microscope appearance. Strongest staining was seen in the hepatocytes. In addition to the Mallory bodies, stain was picked up in a polygonal pattern near the cell membrane in some cells. Normal sera did not show any staining effect on either alcoholic or control specimens. The control specimens occasionally showed a weak polygonal staining of the cell membrane with the antiactin antibody sera. No fluorescence was observed when unlabeled antiserum was used before fluorescein-conjugated antiserum. It is concluded that Mallory bodies in the liver cells of alcoholic patients contain actin-like immunoreactive proteins, and may represent a quantitative alteration of contractile proteins resulting from the disease process.

3503 HYPOGONADISM IN ALCOHOLIC LIVER DISEASE: EVIDENCE FOR A DOUBLE DEFECT. *(E.)* Van Thiel, D. H.; Lester, R.; Sherins, R. J. (Dep. Med., Univ. Pittsburgh, Pa.). *Gastroenterology* 67(6):1188-1199, 1974.

Hypothalamic-pituitary-gonadal function was evaluated in 40 men with a wide spectrum of alcoholic liver disease to identify an anatomic location and biochemical mechanism responsible for observed hypogonadism and feminization. Basal plasma concentrations of follicle-stimulating hormones, luteinizing hormone, estradiol, and testosterone were determined. Hormonal responses to provocative clomiphene and chorionic gonadotropin stimulation were evaluated. Sex steroid-binding globulin capacity was determined to evaluate plasma concentrations of free sex steroid. No correlation between any specific biochemical assessment of the severity of liver disease and the degree of hormonal derangement was noted. However, mean plasma testosterone levels were lower in association with more severe derangements of hepatic histology. Both follicle-stimulating hormone and luteinizing hormone concentrations ranged from normal to moderately elevated with means values (19.8 and 17.2, resp.) statistically elevated when compared to normal means (follicle-stimulating hormone, 11.6 and luteinizing hormone, 8.8). Total plasma estradiol levels were normal or reduced, but the mean (35.6) did not differ from normal. In contrast, plasma testosterone was reduced in half of the men to a mean of 313, which differed significantly from the normal mean of 519. Further magnifying the reduction in testosterone, there was an 8-fold elevation of sex steroid-binding globulin (4.325 compared to normal values of 0.521). Clomiphene response was markedly diminished in the majority with 2/3 failing to produce a 50% increase of either gonadotropin. Similarly, more than 1/3 failed to show a 50% increase in plasma testosterone after exogenous chorionic gonadotropin. Thus, both primary gonadal failure and hypothalmic-pituatary suppression are demonstrable in men with alchoholic liver disease. These abnormalities may result from the ingestion of alchohol. However, function rather than from alcohol ingestion *per se* must not be overlooked. Gonadal atrophy and hypothalmic-pituitary suppression in alcoholic liver disease may result from defective hepatic regulation of estrogenicity. In the face of hepatic damage, nonsteroidal estrogens may be insufficiently metabolized or excreted by the liver, excessive concentrations may accumulate in plasma, and this accumulation may result in target organ stimulation. The possibility that feminization of patients with liver disease results from the accumulation of exogenous rather than endogenous estrogen should be examined. Similarly, the finding of the lowest plasma gonadotropin values and the most severe gonadal failure in those men with the most advanced liver disease may result from increased retention of nonsteroidal estrogen.

3504 THE EFFECT OF CIRRHOSIS ON THE DISPOSITION AND ELIMINATION OF CLINDAMYCIN. *(E.)*

Avant, G. R.; Schenker, S.; Alford, R. H. (Vanderbilt Med. Sch., Nashville, Tenn.). *Am. J. Dig. Dis.* 20(3):223-230, 1975.

The effect of liver disease in patients and of experimental hepatic damage in rats on the disposition and elimination of clindamycin was investigated. Seven patients, average age 41.57 yr, were studied, of whom four had ascites, five had esophageal varices and three had signs of hepatic encephalopthy on earlier occasions. One patient had received 6 capsules of Dyazide (50 mg triamterene and 25 mg hydrochlorothiazide each) during the 3 days prior to the study. The results showed significant impairment of clindamycin elimination in the patients. However, the prolongation of the drug half-life was only modest about 1 hr, 31% over the normal value of 3.42 hr. The half-life in the cirrhotics correlated positively with total serum bilirubin and with SGOT, but not with other liver function tests. It is suggested, assuming higher values for these two tests imply increasing severity of liver disease, that in patients with more extensive hepatic dysfunction greater impairment of clindamycin elimination would be found. Pharmacokinetic analysis of these data suggest that the prolongation of clindamyacin half-life in cirrhosis resulted from decreased drug clearance, not from increases in the volume of distribution. The altered drug clearance in cirrhosis may represent impaired hepatic elimination. Clindamycin serum protein binding in both control and cirrhotic patients was of the order of 79%. The lack of significant decrease of serum binding of clindamycin in cirrhosis is consistent with the absence of a significant increase in the volume of distribution of the drug in this group. Studies were also carried out in Sprague-Dawley rats with hepatic dysfunction caused by CCl_4 pretreatment (0.6 ml/kg) or bile duct ligation. The prolongation of clindamycin half-life obtained with acute hepatic injury of 24 hr duration was highly significant. The data suggest that acute hepatic injury may cause major changes in clindamycin elimination. In conclusion, there was a statistically significant but only modest impairment of clindamycin elimination in this group of alcoholic cirrhosis patients. Animal data suggested that significant changes also could occur with acute hepatic dysfunction and cholestasis.

3505 INCREASED RATE OF ALCOHOL REMOVAL FROM BLOOD WITH ORAL FRUCTOSE AND SUCROSE. *(E.)*

Soterakis, J.; Iber, F. L. (Tufts Univ. Sch. Med., Boston, Mass.). *Am. J. Clin. Nutr.* 28(3):254-257, 1975.

The effect of oral glucose, fructose, and sucrose on the disappearance rate for i.v. administered alcohol was studied in 8 abstinent alcoholic subjects (all males, aged 25-53 yr). The 3 sugars were ingested on separate days in random sequence. After an overnight fast, subjects drank a lemon-flavored solution of glucose (2 g/kg), fructose (2 g/kg), or sucrose (4 g/kg). Alcohol levels were determined at hourly intervals. During ingestion of the sugars, the mean rates of alcohol disappearance were: 19 mg/100ml/hr for glucose; 23.9 mg/100 ml/hr for sucrose, and 25.4 mg/100 ml/hr for fructose. Compared with glucose, both fructose and sucrose increased the rate of removal of alcohol from the blood. Blood fructose levels were similar after the oral dose of fructose or sucrose. Sucrose is more readily available and cheaper to use than fructose and can be used instead of fructose to accelerate alcohol metabolism. Minimal complications were experienced from ingestion of fructose and sucrose. The time necessary to lower blood alcohol levels from 250 mg/100 ml to 40 mg/100 ml should be 3-4 hr shorter with p.o. fructose or sucrose than with glucose. It is noted that blood disappearance of alcohol is not synonymous with sobering or becoming mentally clear.

3506 THE IMPORTANCE OF LIVER BIOPSIES IN THE DIAGNOSIS OF CLINICALLY MANIFEST ALCOHOLIC LIVER DISEASE.

(Ger.) Stotzner, H. (Carl Gustav Carus Med. Acad., Dresden, Germany). *Zentralbl. Alg. Pathol.* 118(4):367-374, 1974.

To determine whether alcoholic liver damage can be diagnosed by histological changes alone, 29 histological features were studied in liver biopsies from 43 patients (34 men and nine women, aged 31-69 yr, mean age 45.9 yr). Of these patients, 33 had consumed between 15 and 450 g/day of alcohol for 4-22 yr (mean 10.2 yr); no accurate information was available on the drinking habits of the remaining 10 patients. Before the biopsies were taken, none of the patients had been given any drugs known to cause liver damage. None of these patients had any clinical evidence of viral hepatitis or hepatobiliary disease. Except for alcoholic hyaline and alcoholic hepatitis, no significant correlations were found between any of the parameters studied. However, five to eight of the following parameters were present in 40 of the 43 patients (93%): cholestasis, giant mitochondria, alcoholic hyaline, focally increased basophilia in the cytoplasm of liver cells, cytoplasmic lakes in the hepatic epithelium, steatosis, siderosis, and fibrosis. In liver biopsies from unselected patients, five or more of the above criteria were found in only two patients who had no history of alcohol consumption. However, both of these patients had been given drugs known to cause liver damage before the biopsies were taken. In the 43 patients whose biopsies were studied in detail, 42 had inflammatory changes in the liver. However, this inflammation fulfilled the criteria for alcoholic hepatitis in only 17 cases. Only 10 of these patients (26%) had evidence of portal hypertension, so that a diagnosis was established in most cases before irreparable liver damage had occurred.

3507 INDUCTION OF DRUG-METABOLIZING ENZYMES IN CHRONIC ALCOHOLICS.

(Ger.) Gundert-Remy, U.; Marquardt, R.; Andritsch, F.; Weber, E. (Med. Clin., Heidelberg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:907-908, 1973.

To determine whether alcohol induces microsomal, drug-metabolizing enzymes in the livers of chronic alcoholics, the half-lives of antipyrine and tolbutamide were measured in plasma from patients hospitalized for chronic alcoholism before and 4 weeks after abstention from alcohol and from nonalcoholic controls. Antipyrine (15 mg/kg) was administered to five alcoholics and five controls, and tolbutamide, to two alcoholics and six controls. None of the alcoholics were given any drugs for at least 3 weeks before the second test. The mean half-lives of antipyrine were lower in alcoholics than in nonalcoholic controls, suggesting that alcohol does induce drug-metabolizing enzymes in the livers of these patients. However, when the two tests were compared for individual alcoholics, half-lives increased in only two of five patients. Changes in the half-lives of antipyrine were of the same order of magnitude in alcoholics (-0.6 hr) and controls (-0.4 hr). Similar results were obtained with tolbutamide. It is concluded that alcohol does not induce drug-metabolizing enzymes in the livers of chronic alcoholics.

3508 GLYCOGENOLYSIS AND GLUCONEOGENESIS IN HUMAN LIVER AS INFLUENCED BY ETHANOL.

(Ger.) Dietze, G.; Wicklmayr, M.; Grunst, J.; Hepp, K. D.; Braun, S.; Mehnert, H. (Schwabing Hosp., Munich, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:911-914, 1973.

Catheters were inserted into the hepatic veins and needles into the femoral arteries of 14 normal subjects who had fasted for 14 hr. After a 30 min basal period, alcohol was infused into the cubital vein at a rate of 15 g/5 min which was later decreased to 0.2 g/min. Blood samples were taken before alcohol infusion and at 10 min intervals for 1 hr thereafter to determine insulin, glucose, lactate, pyruvate, β-hydroxybutyrate, acetoacetic acid, glycerol, and amino acids. Similar determinations were performed on six controls who received i.v. infusions of physiological saline. Liver blood flow was measured throughout with an ^{133}Xe inhalation technique. Within 10 min after alcohol infusions were begun, ethanol concentrations in the femoral artery and hepatic vein reached a steady state at a concentration of 9 mM, and glucose production increased by 60%. After 50 min, glucose production decreased to values which were lower than those in the controls. Glycerol utilization increased significantly after 30 min and reached initial values after 50 min, while alanine utilization increased immediately after alcohol infusions were begun and remained elevated for about 30 min; a significant decrease occurred 20 min later. The uptake of lactate ceased entirely during administration of alcohol, and lactate production began shortly after alcohol infusions began. By assuming that lactate, alanine, and glycerol are used only to produce glucose and are converted into glucose in stochiometric proportions, 40% of the glucose produced in the liver under basal conditions results from gluconeogenesis and 60% from glycogenolysis. When alcohol is infused, gluconeogenesis decreases by 75% and remains essentially unchanged throughout the observation period. Thus, the increase in glucose production induced by ethanol can be attributed to a large increase in the rate of glycogenolysis.

3509 ACQUIRED DYSERYTHROPOIETIC ANEMIA IN CHRONIC LIVER DISEASE (ALCOHOLIC CIRRHOSIS). *(Ger.)* Riedler, G. F.; Schmid, M. (Waid Munic. Hosp., Zurich, Switzerland). *Schweiz. Med. Wschr.* 104(39):1393, 1974.

Hematological test findings in three patients with serious alcoholic liver cirrhosis are presented with respect to the pathogenesis of acquired dyserythropoietic anemia. Typical macrocytic anemia with target cells and stomatocytes, and increased rate of erythropoiesis with normal sideroblasts were detected in all three patients. The first patient (aged 44 yr, male) additionally showed acquired, refractory anemia, bizarre karyoclasis, polynuclear erythroblasts with filamentous interchromatin bridges, and reduced reticulocyte count in the bone marrow. ^{59}Fe Incorporation was 18%, and the calculated ineffective erythropoiesis was 63.37 mg/day against a normal range of 6-26 mg/day. The second patient (aged 61 yr, male) showed a reduced variety of karyoclases, and few polynuclear erythroblasts. The iron incorporation amounted to 51%. Increased erythropoiesis and normal iron incorporation were found in a third, 59-yr-old female patient. The PAS, ham and sucrose tests were negative in all patients. The findings indicate acquired dyserythropoietic anemia in the first patient, and the comparison with the other patients suggests a smooth transition from pure ineffective erythropoiesis to dyserythropoietic anemia in patients with serious chronic liver disease.

3510 PRELIMINARY OBSERVATION OF d-PENICILLAMINE THERAPY IN ACUTE ALCOHOLIC LIVER DISEASE. *(E.)* Resnick, R. H.; Biotnott, J.; Iber, F. L.; Makopour, H.; Cerda, J. J. (Lemuel Shattuck Hosp., Boston, Mass.). *Digestion* 11(3/4):257-265, 1974.

The effect of penicillamine on the mortality rate, hepatic dysfunction, and histopathology of acute alcoholic liver disease was studied in a prospective controlled trial. Hospitalized patients with this condition (19) were given penicillamine (250 mg 4 times a day) p.o. for 8 weeks, and 21 similar patients were given a placebo for the same period of time. The penicillamine and placebo groups did not differ significantly in terms of mortality rate or longevity; in each group, the deaths were due to hepatic failure characterized by increasing jaundice and ascites. Although total bilirubin and SGOT values improved significantly within each group during the study, the two groups did not differ significantly from each other in terms of hepatic function. However, compared with the placebo group, the penicillamine group showed a greater reduction in total and active fibrosis and cellular injury during the 8-week treatment program. Determinations of histologic diagnosis also suggested improvement consequent to penicillamine treatment, although the differences between the penicillamine and placebo groups in this respect were not significant. Since penicillamine failed to improve survival rates or liver function parameters in these patient, the routine use of this drug in the management of alcoholic hepatitis cannot be justified. However, this agent may find ultimate use in the treatment of chronic hepatic disorders associated with fibrogenesis.

LIVER AND BILIARY TRACT

Cirrhosis

3519 THE PREDICTION OF THE OUTCOME OF PORTACAVEL [SIC!] SHUNT USING BROMSULPHTHALEIN (BSP): A RETROSPECTIVE ASPECT. *(E.)* Turner, J.; Cuschieri, A.; Shields, R. (Dept. Surg., Univ. Liverpool, England). *Br. J. Surg.* 61(10):828-831, 1974.

The use of compartmental BSP kinetics to predict the outcome of portacaval shunt operations was investigated in 17 patients who underwent elective portacaval shunt. The indication for operation in each case was previous hemorrhage from esophageal varices. In all patients the portal hypertension was the result of hepatic cirrhosis. The survival range after operation was 2 weeks to 14 yr. BSP (3-4 mg/kg) was injected i.v. after an overnight fast. Venous blood was obtained from the other arm through a wide bore cannula, initially at 2-min intervals, later at 5-min intervals, and finally at 10-min intervals over a period of 80 min. In each sample the plasma concentration was determined spectrophotometrically. The equivalent liver volume is given by aV/b, where V is the plasma volume, a is the rate constant for the movement of BSP from plasma to liver, and b, the rate constant for the movement of BSP from liver to plasma (a and b are derived from the plasma disappearance curve of BSP when plotted on semilogarithmic paper). The equivalent liver volume is an expression of the storage capacity of the liver for BSP and is the volume of plasma which would contain the same amount of BSP as the liver. The mean value for equivalent liver volume in the 17 patients studied was 0.59 liter/kg. In those in whom the clinical outcome of portacaval shunt was regarded as good (six patients) the preoperative equivalent liver volume in every case but one was more than 0.75 liter/kg, whereas among those in whom the results were poor, the equivalent liver volume was less than o.75 liter/kg. It appears that a patient with an equivalent liver volume of less than 0.5 liter/kg before operation had a high risk of dying or developing chronic hepatic failure if he survived the operation. Although these results are from a retrospective study of a small number of patients, they suggest that the equivalent liver volume may be of considerable predictive value for shunt operation.

3520 INTRACISTERNAL HYALINE IN HUMAN BIOPSIES. *(Ger.)* Pfeifer, U.; Klinge, O. (Pathol. Inst., Univ. Wurzburg, Germany). *Verh. Dtsch. Ges. Pathol.* 57:438, 1973.

Unusual cytoplasmic hyaline inclusions were found in the livers of two patients with cirrhosis and in one with an unclassifiable form of chronic progressive parenchymal damage. In one cirrhotic they consisted of many spheres, up to 15 μ in diameter, which stained positively with PAS reagent and were resistant to diastase. In the second cirrhotic, the inclusions were irregular in form and PAS-negative. PAS-negative hyaline inclusions occurred primarily at the periphery of the lobules and measured about 7 μ in diameter in the third case. In all three cases, Laqueur's acid fuchsin stain was negative. Electron microscopy showed that some of the inclusions were surrounded by a membrane, studded in places with ribosomes and bound directly to cisternae in the rough endoplasmic reticulum. Lipid droplets were present in the inclusions in the first two cases. These findings suggest that there is a disorder in the transport of protein in these hyaline inclusions.

3521 THE ASSOCIATION OF SYPHILIS WITH CIRRHOSIS: THE ROLE OF ALCOHOL AND SERUM HEPATITIS. *(E.)* Sadikali, F. (Makerere Univ. Med. Sch., Kampala, Uganda). *Postgrad. Med. J.* 51(592):69-73, 1975.

The role of syphilis and alcohol was investigated in a prospective study of 80 patients with cirrhosis of the liver in Uganda. Results were correlated with the histological type of cirrhosis, and serological tests for hepatitis B antigen (HB Ag). Eighteen (22.5%) patients with histologically-proven cirrhosis had positive seriology for syphilis (VDRL and TPI). A high incidence of alcoholism (80%) and syphilis (60%) was found in patients with micronodular cirrhosis who were all negative for HB Ag. By contrast, HB Ag was detected in 37% of patients with macronodular cirrhosis who had a much smaller incidence of syphilis and alcoholism. Although chronic infection with hepatitis B virus related to HB Ag appears to be an important factor in the pathogenesis of cirrhosis in at least 30% of cases, infection acquired during past treatment for syphilis is not an important cause of the association of syphilis with cirrhosis in this population. Subdivision of patients with cirrhosis into those with and those without a history of severe alcohol abuse showed that the difference between the incidence of syphilis in the two groups is statistically significant. However, evidence of syphilis in association with non-alcoholic as well as alcoholic cirrhosis in this and other previously reported series suggests that the association between the two diseases cannot be entirely explained through the common factor of alcoholism, and other factors may also be responsible.

3522 PRIMARY BILIARY CIRRHOSIS IN BROTHERS. *(E.)* Bown, R.; Clark, M. L.; Doniach, D. (St. Bartholomew's Hosp., London, England). *Postgrad. Med. J.* 51(592):110-115, 1975.

Case histories of two brothers with classical primary biliary cirrhosis are presented. Both patients, who presented at age 58, developed abnormal liver function tests, jaundice, hepatomegaly and portal hypertension which progressed eventually to coma and death. Both had antimitochondrial antibodies while one also exhibited smooth muscle antibodies. One became Australia antigen-positive terminally. Liver biopsies revealed advanced primary biliary cirrhosis. Both patients also developed an associated keratoconjunctivitis sicca. In one, renal tubular acidosis and ruptured esophageal varices occurred following lactulose therapy. Screening of the family revealed three relatives with overt thyroid disease, one sister with a high anti-thyroid antibody titer, and several other members with autoimmune diseases or auto-antibodies. This representes the first known report of primary biliary cirrhosis in brothers.

3523 PHENOBARBITAL EFFECTS IN CHOLESTATIC LIVER DISEASE.

(E.) Bloomer, J. R.; Boyer, J. L. (Yale Univ. Sch. Med., New Haven, Conn.). *Ann. Intern. Med.* 82(3):1-5, 1975.

The effects of short-term phenobarbital administration on liver function and disease progression were studied in seven patients with primary biliary cirrhosis, two with sclerosing cholangitis, three with intrahepatic biliary hypoplasia and three with cholestatic hepatitis. Phenobarbital was given p.o. 120-250 mg/day for 1-5 months. Except for those patients with cholestatic hepatitis, total serum bilirubin declined during therapy from a mean of 7.0 mg% to 3.6 mg% with concomitant relief of pruritus. Some patients also showed reduced serum bile acid concentrations which, however, did not correlate with the extent of decrease in bilirubin. The mean serum cholate:chenodeoxycholate ratio decreased from 2.1 to 1.7, both substances declining during therapy. Although some patients showed slight improvement in BSP excretion and hepatic uptake of ^{131}I-rose benegal, the changes were not significant ($P > 0.10$). Serum cholesterol concentrations and other hepatic function tests also were not significantly changed except for alkaline phosphatase which rose in 12 of 15 patients. It is concluded that short-term phenobarbital administration is helpful in selected patients with intrahepatic cholestasis.

3524 RELATION BETWEEN MORPHOLOGY AND FUNCTION IN PRETERMINAL DIGITAL CIRCULATION IN CIRRHOSIS. II.

(It.) Andreuzzi, P.; Curri, S. B.; Redaelli, T.; Cantoni, L. (Maggiore Ca' Granda Hosp.; Milan, Italy). *Minerva Med.* 65(40):2287-2295, 1974.

The relation between morphology and function in preterminal digital circulation was studied in 16 patients with cirrhosis of the liver by oscillographic, plethysmographic, and rheographic methods. All patients showed serious, bioptically demonstrated changes in the arteriovenous anastomoses. Abnormal plethysmograms in 10 cases, considerable reduction of the pulse volume with reduced or suppressed dicrotism, and reduced arterial flow rate following the venous congestion test in 5 cases were observed. The marked vasomotor hypertonia was dispelled by indirect heating. The findings indicate the morphological and functional involvement of the digital derivative circulation in liver cirrhosis. While the changes observed are similar to those found in physiological senility and during the initial stages of peripheral vascular diseases, the arteriosclerotic and atheromatous phenomena are less severe in cirrhosis.

3525 HYPERNATREMIA FOLLOWING GASTROINTESTINAL BLEEDING IN CIRRHOSIS WITH ASCITES.

(E.) Rodes, J.; Arroyo, V.; Bordas, J. M.; Bruguera, M. (Clin. Prov. Hosp., Univ. Barcelona, Spain). *Am. J. Dig. Dis.* 20(2):127-133, 1975.

Plasma hypernatremia and hyperosmolality produced by osmotic diuresis following gastrointestinal bleeding, occurred 6 times in 3 patients. In each case the patient presented with cirrhosis and ascites. The relationship of the diuresis, and increase in blood urea concentration and excretion, and the close temporal relationship between the episodes of diuresis and the gastrointestinal bleeding suggested that the diuresis was due to increase in blood urea from intestinal absorption of blood. Hypernatremia results in cirrhosis and ascites because of low natriuresis due to low distal sodium resorption probably resulting from hyperaldosteronism. It is suggested that osmotic diuresis be suspected whenever there is polyuria and azotemia associated with intestinal bleeding.

3526 REDUCED SERUM SOMATOMEDIN ACTIVITY IN PATIENTS WITH CHRONIC LIVER DISEASE.

(E.) Wu, A.; Grant, D. B.; Hambley, J.; Levi, A. J. (Northwick Park Hosp. Clin. Res. Cent., Harrow, England). *Clin. Sci. Mol. Med.* 47(4):359-366, 1974.

Serum somatomedin activity in 21 patients with liver disease was studied in relation to fasting serum growth hormone levels and biochemical liver function tests. Ten patients had micronodular cirrhosis, 8 hepatofibrosis, 2 fatty change, and 1 hepatoma. Blood samples were taken by venipuncture after an overnight fast, and somatomedin activity was estimated by chick cartilage assay. Serum growth hormone was estimated by double-antibody radioimmunoassay. The serum somatomedin values were low in 9 patients with cirrhosis (0.042-0.65), 1 with hepatofibrosis (0.27) and the 1 with hepatoma (10.10), relative to values from normal controls. Of these 11, the lowest values were from 5 that had ascites (0.04-0.62). Serum from the patients with low values had no inhibitory effect on control serum activity. Seven of the low value patients had serum growth hormone levels above normal, 6 had low serum albumin (23-33 g/liter), and 8 had high serum total bilirubin (16-117 μM/liter). A significant negative correlation was found between somatomedin activity and alkaline phosphatase. The inverse relationship between somatomedin and growth hormone levels, and the correlation between low somatomedin activity and abnormal liver function tests suggest that the liver is an important site for somatomedin synthesis.

3527 COLLAGEN BIOSYNTHESIS IN LIVER DISEASE OF THE ALCOHOLIC.

(E.) Chen, T. S. N.; Leevy, C. M. (Coll. Med. Dent. N.J., Newark). *J. Lab. Clin. Med.* 85(1):103-112, 1975.

Patterns of collagen synthesis were investigated in alcoholic patients with fatty liver (6), alcoholic hepatitis (4), active Laennec's cirrhosis (8), and normal liver (3). Biopsy specimens were taken 72 hr after treatment for possible vitamin or mineral defiencies. Collagen biosynthesis was measured by *in vitro* incorporation of ^{3}H-proline into the salt soluble and salt insoluble collagen fractions. In one set of experiments, 21.7 μM/ml of ethanol was added to the incubation medium, and incubated 2 hr. Saline was used as a control. Autoradiographic studies of each liver specimen were made, some in which tissues were first digested with collagenase prior to coating with emulsion. It was found that the salt-soluble:salt-insoluble collagen ratio was decreased in both alcoholic hepatitis and cirrhosis, but unchanged in fatty liver. The ^{3}H-proline uptake was significantly increased in fatty liver, hepatitis and cirrhosis in both salt-soluble and insoluble fractions while ^{3}H-hydroxyproline uptake was increased 5-fold in cirrhosis in the salt-soluble collagen and increased in the hepatitis and cirrhosis in the salt-insoluble collagen. The *in vitro* ethanol caused a significant increase in both the ^{3}H-proline and hydroxyproline in the soluble and insoluble fractions in both hepatitis and cirrhosis. In the autoradiographic studies, normal specimens showed sparse labeling of the Kupffer cells, while fatty liver showed a concentration of label in the portal areas and in the hepatocytes. The hepatitis specimens showed labeling of mainly the portal and centrilobular areas, concentrating over many cell types, and the cirrhosis specimens showed labeling in the portal areas, mainly over mesenchymal cells, ductular cells and collagen fibers. It is concluded that salt-insoluble collagen synthesis is increased in alcohol-induced hepatitis and cirrhosis, due to liver cell damage and to the presence of ethanol.

3528 THE FIBRINOLYTIC ENZYME SYSTEM IN ACUTE AND CHRONIC LIVER INJURY.

(E.) Mowat, N. A. G.; Brunt, P. W.; Ogston, D. (Dep. Med., Univ. Aberdeen, Scotland). *Acta Haematol. (Basel)* 52(5): 289-293, 1974.

The major components of the fibrinolytic enzyme system were compared in 35 patients with hepatic cirrhosis (10), alcoholic liver disease (9), primary biliary cirrhosis (9), and chronic active hepatitis (6). In the hepatic cirrhosis patients, although increased plasma fibrinolytic activity was seen in some, the mean level was not significantly different from control values (373 mg/100 ml). The mean plasminogen level, however, was significantly lower (3.9 *versus* 4.4 casein μ/ml), and both α_1-antitrypsin (379 mg/100 ml) and α_2-macroglobulin (399 mg/100 ml) were increased over control values of 275 and 271, resp. The chronic active hepatitis patients were similar to the previous group in their increased activator (5.8 U) and reduced plasminogen activity (3.4 casein μ/ml). In contrast, those with alcoholic liver disease showed decreased activator (2.6 U) and normal plasminogen activities. The patients with primary biliary cirrhosis had low mean activator levels (2.7 U) while fibrinogen (438 mg/100 ml), α_2-macroglobulin levels (364 mg/100 ml) were all significantly elevated. It is concluded that fatty infiltration of the liver is accompanied by the same changes that occur after injury and many acute illnesses: decreased fibrinolytic activity and increased levels of fibrinogen and α_1-antitrypsin. Also, previous findings of reduced fibrinolytic activity and increased fibrinogen levels in cases of primary biliary cirrhosis are confirmed.

3529 LIVER CIRRHOSIS: IMMUNOFLUORESCENCE AND BIOCHEMICAL STUDIES DEMONSTRATE TWO TYPES OF COLLAGEN.

(E.) Gay, S.; Fietzek, P. P.; Remberger, K.; Eder, M.; Kuhn, K. (Max-Planck Inst. Biochem., Munich, Germany). *Klin. Wochenschr.* 53(5): 205-208, 1975.

The collagen synthesized by small- and large-noduled liver cirrhoses was characterized immunohistologically and biochemically. The collagen was prepared from the livers of a 51-yr-old woman with small-noduled liver cirrhosis and a 73-yr-old man with large-noduled liver cirrhosis and liver carcinoma of both hepatocellular and cholangiocellular type. The fibrous septa of both livers showed specific fluorescence with anti-type III collagen antibodies, as did the fibrosing septa of the cholangiocellular liver carcinoma. No fluorescence was seen with anti-type I and II collagen antibodies or normal serum. Pepsin solubilization of the cirrhotic livers yielded two fractions: 40% of the total collagen precipitated at 1.5 M NaCl, and 60% precipated at 2.5 M NaCl. The 1.5 M NaCl precipitate was classified as type III collagen according to its electron microscope characteristics, chromatographic behavior, and pattern of CNBr peptide. Although the 2.5 M NaCl precipitate appeared to be type I collagen under the electron microscope, no reaction could be obtained with anti-type I antibodies and the chromatographic behavior was different from that of type I collagen isolated from the skin. The results suggest an increased rate of biosynthesis of both types of collagen under pathological conditions. The increased type III collagen in the cirrhotic livers was due to hepatic cell necrosis and increased synthesis in the periductular and portal area; the 2.5 M NaCl precipitate was apparently synthesized in the proliferating fibroblasts in the portal tracts. The process of polymerization and possible pathological cross-linking of collagen fibrils may be initiated and enhanced by substances from necrotic hepatocytes; therefore, the balance of interaction between epithelial and mesenchymal cells might be disturbed.

3530 SPONTANEOUS REVERSAL OF PORTAL BLOOD FLOW: THE CASE FOR AND AGAINST ITS OCCURRENCE IN PATIENTS WITH CIRRHOSIS OF THE LIVER.

(E.) Moreno, A. H.; Burchell, A. R.; Reddy, R. V.; Steen, J. A.; Panke, W. F.; Nealon, T. F. (St. Vincent's Hosp., New York, N.Y.). *Ann. Surg.* 181(3):346-358, 1975.

An analysis was made of the evidence for and against the occurrence of spontaneous reversal of portal flow in cirrhosis of the liver. The evidence examined was obtained from an extensive review of the literature including manometric studies, radioactive tracer studies, radiologic studies, and actual measurements of magnitude and direction of portal blood flow. A physical analysis of manometric studies demonstrated that the occluded portal pressures could not be used to construct a hydraulic gradient for portal flow. The evidence derived from radioactive tracer and radiologic studies was also examined and found weak, with conflicting results in the radiologic studies. Actual measurements of magnitude and direction of portal flow provided impressive evidence against the occurrence of spontaneous reversal of portal flow in cirrhosis. The findings suggest that unless new and convincing evidence is provided, it may not serve the best interests of medicine and of patients to continue accepting the unproven phenomenon of spontaneous reversal of portal flow in cirrhosis.

3531 PORTACAVAL SHUNT IN FOUR PATIENTS WITH HOMOZYGOUS HYPERCHOLESTEROLAEMIA. *(E.)*

Stein, E. A.; Mieny, C.; Spitz, L.; Saaron, I.; Pettifor, J.; Heimann, K. W.; Bersohn, I.; Dinner, M. (South African Inst. Med. Res., Johannesburg). *Lancet* 1(7911):832-835, 1975.

The early results of portacaval shunt in four patients with homozygous hyperbetalipoproteinemia are described. The patients, all of whom proved resistant to intensive dietary and drug therapy, were a 7-yr-old boy, a 27-yr-old man, a 16-yr-old girl, and a 10-yr-old boy. Prior to portacaval shunt, all patients were removed from medical treatment and submitted to total parenteral alimentation. During the first 2 weeks they were given a casein hydrolysate, dextrose, electrolyte, and vitamin infusion; during the third week, this was supplemented with infusion of a fat emulsion, the fat content of which was gradually increased to 2 g/kg. End-to-end portacaval shunt was performed at the end of the third week. During the period of parenteral alimentation, the serum cholesterol decreased significantly in all four patients, although during the administration of the fat emulsion, one patient experienced a rise in cholesterol. Postoperatively, the size of xanthomas decreased in all cases; the serum cholesterol levels rose above those achieved during hyperalimentation, and this rise continued for up to 3 months before further reductions were observed. Postoperative triglyceride levels were normal in all patients, and in most patients, bruits decreased in intensity. Improvements in patients with angina were considerable. None of the patients experienced any ill-effects postoperatively. The results indicate that it would be premature to consider all patients with homozygous hypercholesterolemia for portacaval shunt.

3532 SULFATION AND RENAL EXCRETION OF BILE SALTS IN PATIENTS WITH CIRRHOSIS OF THE LIVER. *(E.)*

Stiehl, A.; Earnest, D. L.; Admirand, W. H. (San Francisco Gen. Hosp., Calif.). *Gastroenterology* 68(3):534-544, 1975.

Bile salt sulfation was evaluated in 17 patients with cirrhosis of the liver to determine the importance of that metabolic pathway. Analyses were made of sulfated and nonsulfated free and glycine or taurine-conjugated bile salts in serum, urine, and bile. Gas-liquid chromatography, isotopic studies, and infrared spectroscopy were also carried out. Of the urinary bile salts, 56% were sulfated: 24% of the cholate, 76% of the chenodeoxycholate, 85% of the deoxycholate, and 100% of the lithocholate. Neither sulfated nor nonsulfated bile salts could be detected in urine from two normal subjects. Of bile salts synthesized in the liver, 3-12% were excreted in urine. Sulfated bile salts represented 4-5% of the total bile salts in serum and 7-10% of the total bile salts in bile. Approximately 95% of both sulfated and nonsulfated bile salts in serum, urine, and bile were conjugated with glycine and taurine. Renal clearance of cholate was more than 3 times greater than that of chenodeoxycholate or deoxycholate. Renal clearance of sulfated bile salts was 20-200 times greater than that of the corresponding nonsulfated bile salts. With the exception of serum bilirubin, no direct correlation was found between severity of liver disease and concentrations of bile salts in peripheral blood. The results demonstrate sulfation of bile salts in patients with cirrhosis and the excretion of the sulfated compounds in urine.

3533 LIVER FAILURE AFTER JEJUNOILEAL SHUNT. *(E.)*

Andrassay, R. J.; Haff, R. C.; Lobritz, R. W. (Wilford Hall US Air Force Med. Cent., Lackland Air Force Base, Texas). *Arch. Surg.* 110(3): 332-334, 1975.

An unusual case of liver failure resulting from a jejunoileal shunt is presented. A 41-yr-old woman underwent jejunoileal bypass for morbid obesity, with 35.6 cm of jejunum distal to the ligament of Treitz anastomosed end-to-end to 10.2 cm of ileum proximal to the ileocecal valve. Preoperative evaluation showed normal liver scan, liver function and BSP test results. About 1 yr later she was hospitalized for polyarthritis of unknown etiology. Liver function tests showed elevated alkaline phosphatase (27 King-Armstrong U/100 ml) and serum glutamic oxaloacetic transaminase (153 mμ/ml) values. Liver biopsy showed severe fatty infiltration, marked portal fibrosis with entrapment of hepatocytes, and portal triaditis. Hepatocytic necrosis was seen in some areas. After a month the polyarthritis had spontaneously cleared, but liver function tests showed an elevated level of alkaline phosphatase (320 IU), and elevated levels of SGOT (150 mμ/ml), lactic dehydrogenase (210 IU/liter), creatine phosphokinase (25 IU), and bilirubin (0.8 mg/100 ml). Surgery was performed and normal intestinal anatomy restored. Liver function values returned to normal within 2 months. Biopsy showed complete resolution of the fatty infiltration and hepatocytic necrosis. The case supports the previously proposed potential hazard of liver damage after ileojejunal bypass. It is suggested that these patients be maintained on a high protein and vitamin supplemented diet with avoidance of alcohol, and be kept under close observation for at least 2 yr after surgery.

3534 CLINICAL PHYSIOLOGIC APPROACH TO THE PATIENT WITH PORTAL HYPERTENSION. *(E.)* Chiandussi, L. (Univ. Turin, Italy). *Bull. NY Acad. Sci.* 51(4);557-564, 1975.

Some of the major problems which are encountered in connection with the new techniques available for the clinical investigation of portal hypertension are reviewed. These techniques include direct catheterization of the left branch of the portal vein *via* the round ligament of the liver, catheterization of the celiac trunk and the superior mesenteric artery, and simultaneous catheterization of a main hepatic vein and the left branch of the portal vein. Portal hypertension may arise from thrombosis of the portal vein (extrahepatic portal hypertension), partial occlusion of the hepatic veins (Budd-Chiari syndrome), or, most frequently, intrahepatic block (intrahepatic portal hypertension). Intrahepatic portal hypertension can occur as the result of postsinusoidal block (e.g., veno-occlusive disease, alcoholic hepatitis), intrahepatic block (e.g., cirrhosis, Wilson's disease), or presinusoidal and sinusoidal block (e.g., steatosis, tumors, schistosomiasis, infiltrative diseases, obliterative portal venopathy). Direct catheterization of the portal vein and catheterization of the celiac trunk and the superior mesenteric artery have also contributed to the diagnosis and clinical study of patients with portal hypertension. For example, there is evidence that diversion of portal blood from the liver influences hepatic function and, therefore, survival; the development of reliable methods for the preoperative determination of portal flow in intact patients makes it possible to test this hypothesis by large-scale prospective, controlled studies. Multicentric prospective controlled studied are also needed for: the determination of the survival rate and incidence of encephalopathy in cirrhotics who undergo distal or selective shunt or end-to-side portacaval shunt; the critical evaluation of the medical management of bleeding esophageal varices; and evaluation of the modified Sengstaken-Blackemore tube and the continous infusion of vasopressin or felypressin into the superior mesenteric artery.

3535 CHILDHOOD CRYPTOGENIC CIRRHOSIS AND ANTIMICROSOMAL ANTIBODIES: A NEW SEROLOGICAL MARKER? *(Fr.)* Joannard, A.; Bost, M.; Micouin, C.; Bensa, J. C.; Varloteaux, C.; Beaudoing, A. (Univ. Hosp. Ctr., Grenoble, France). *Pediatrie* 29(6):607-613, 1974.

A 10-yr-old girl, who had been in good health, developed jaundice and signs of portal hypertension when she was hospitalized with pneumococcal pneumonia. Liver function was severely disturbed, and there were signs of hypersplenism. In addition to hypergammaglobulinemia, the IgG concentration was very high (40 g/liter) and the IgA concentration very low (0.30 g/liter). Antimicrosomal antibodies for the liver and kidneys were detected in high titers (1/1000) in the serum by indirect immunofluorescence; they were also present in ascites fluid, but in lower titers. Radiological examinations revealed esophageal varices, and the portal pressure was 50 cm H_2O; no evidence of a prehepatic block was found. At laparoscopy a diagnosis of macronodular cirrhosis was confirmed. A splenectomy was performed in conjunction with an end-to-side portacaval anastomosis 21 days after onset of symptoms. For 6 months after surgery the patient received decreasing doses of corticosteroids. Serum protein levels improved together with improvements in the clinical and biological findings; antimicrosomal antibody titers decreased to 1/200. When corticosteroids were discontinued for 9.5 months, the patient again developed ascites and jaundice, biological findings became abnormal, and antimicrosomal antibody titers increased to 1/1000. Since diuretics and corticosteroids have been reinstituted, all biological findings have improved with the exception of serum alkaline phosphatase levels. Antimicrosomal antibody titers have decreased to less than 1/10. These autoantibodies are relatively rare and have been previously reported in high titers only in 11 young patients with chronic active hepatitis, 15 with various liver diseases, and 6 with extrahepatic or undiagnosed diseases.

3536 CONNECTIVE TISSUE ALKALINE PHOSPHATASE IN THE SERUM: A CRITERION OF THE ACTIVITY OF CHRONIC LIVER DISEASES. *(Ger.)* Liebe, S.; Petzold, H.; Rogos, R. (Dep. Med., Karl Marx Univ., Leipzig, Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 34(1): 23-26, 1974.

After dialyzing 20 μl serum against potassium phosphate buffer (0.01 M, pH 7.2) and adding 100 μl of a 20% aqueous sucrose solution, isoenzymes of alkaline phosphatase were separated by electrophoresis in 7% polyacrylamide gel. These studies were performed on fasting sera from 21 patients with cirrhosis and seven patients with chronic aggressive hepatitis undergoing transformation into cirrhosis. Small intestine alkaline phosphatase was detected in sera from 1/2 of these patients, but another isoenzyme, whose electrophoretic mobility was intermediate between that of hepatic and small intestine phosphatases, was present in sera from 2/3 of all patients. In some sera, the latter component was found in combination with the small intestine isoenzyme, while in others, it occurred alone. This isoenzyme has not previously been described in sera from patients with liver disease. Although some literature reports have indicated that this is bone alkaline phosphatase, none of the patients studied had any evidence of skeletal disease. This isoenzyme occurred only in sera from patients whose liver biopsies had strong alkaline phosphatase reactions in the connective tissue. This suggests that the intermediate isoenzyme originates in active connective tissue in the liver, passes over into the serum, and can be detected there by electrophoresis. Since connective tissue proliferation is regarded as a criterion for the activity of cirrhosis, the detection of connective tissue phosphatase in the serum can be considered indirect evidence of active cirrhosis.

3537 PLASMA PHOSPHATIDE PATTERN IN ACUTE AND CHRONIC LIVER DISEASE. *(Ger.)* Jipp, P.; Ravens, K. G.; Salm, M. (Med. Clin., Univ. Kiel, Germany). *Klin. Wochenschr.* 52(16):759-762, 1974.

Total phospholipid concentrations and the concentrations of lysolecithin, sphingomyelin, lecithin, and phosphatidylethanolamine were determined by thin-layer chromatography in plasma from 18 patients (eight women and 10 men; mean age 45 yr) with acute hepatitis; 37 patients (13 women and 24 men; mean age 57 yr) with cirrhosis; 10 patients (one woman and nine men; mean age 44 yr) with fatty liver and 30 normal controls (11 women and 19 men; mean age 40 yr). Except for an increase in the mean concentration of phosphatidylethanolamine, the phospholipid pattern was normal in patients with fatty liver. While no significant difference was found between the mean concentrations of total plasma phospholipids in cirrhotics and controls, the mean lysolecithin concentration was decreased and the mean phosphatidylethanolamine concentration increased in cirrhosis. Two weeks after the onset of acute hepatitis, the mean concentrations of total phospholipids, sphingomyelin, lecithin, and phosphatidylethanolamine were increased and the mean concentration of lysolecithin was decreased. No correlations were found between changes in phospholipid levels and the results of liver function tests. The lysolecithin: lecithin ratio was significantly lower in patients with acute hepatitis and cirrhosis than in controls. Differences in changes occurring in lecithin and lysolecithin are considered to be the result of a decrease in lecithin-cholesterol acyl transferase activity.

3538 CLINICAL STUDY ON THE COMPETITIVE HEPATIC EXCRETION OF BILIRUBIN AND SULFOBROMOPHTHALEIN. *(Sp.)* Alves, J.; Santolaria, F.; Cabarcos, A.; Huguet, R.; Bruguera, J. A.; Liso, P. (Fac. Med., Univ. Navarra, Pamplona, Spain). *Rev. Esp. Enferm. Apar. Dig.* 44(7):687-696, 1974.

The 45-min BSP retention test was performed on five patients with liver disease and nine controls by slow i. v. injection of 5 mg/kg BSP. Bilirubin levels were measured before injection of BSP and 72 hr later. These studies were performed on one patient with extrahepatic obstructive jaundice, two with alcoholic cirrhosis, one with chronic aggressive hepatitis, and one with cryptogenic cirrhosis. In the patient with extrahepatic obstructive jaundice, injection of BSP increased total serum bilirubin levels by 36.8% (36.8% for direct, 38.4% for indirect). In contrast, no appreciable change occurred in serum bilirubin levels in the other four patients with liver disease, whether they were jaundiced or not, or in the controls. No correlations were found between increases in bilirubin levels, when they occurred, and the initial bilirubin values in jaundiced patients, the degree of hepatomegaly, or the results of liver function tests. In extrahepatic obstructive jaundice, increases in serum BSP and bilirubin levels are due to competition between these two substances in the hepatocytes. In patients with intrahepatic disease, the liver has lost its ability to conjugate and transport BSP but not bilirubin.

3539 α_1-ANTITRYPSIN DEFICIENCY IN INFANTS: CLINICAL, BIOCHEMICAL, MORPHOLOGICAL, IMMUNOHISTOCHEMICAL, AND GENETIC FINDINGS IN TWO INFANTS. *(Ger.)* Exss, R.; Rotthauwe, H. W.; Schattenberg, P. J.; Totovic, V.; Muller, R.; Sennekamp, J.; Benkmann, H. G.; Goedde, H. S. (Pediatr. Clin., Univ. Bonn, Germany). *Dtsch. Med. Wochenschr.* 100(6):222-228, 1975.

Case reports are presented for two infants who developed cholestatic jaundice by age 3 and 6 weeks, resp. Examination of liver biopsies showed the presence of globular eosinophilic inclusions in the cytoplasm of many parenchymal cells and perilobular fibrosis. The inclusions gave a positive reaction with PAS reagent, were diastase-resistant, and stained selectively with fluorescein-labeled rabbit antihuman α_1-antitrypsin. Under the electron microscope, these deposits of α_1-antitrypsin appeared to be amorphous material in dilated cisternae of the endoplasmic reticulum. Family studies of serum α_1-antitrypsin levels showed that both infants were homozygous for the protease inhibitor (Pi) gene. In one case, the patient's father and paternal aunt were also homozygotes, while the mother, paternal grandparents, and maternal grandmother were heterozygotes. In the other case, the parents, paternal grandmother, and maternal grandfather were heterozygotes. These findings are consistent with an autosomal codominant inheritance. Except for slight hepatomegaly, neither patient had clinical symptoms at age 1 yr. However, serum transaminase and γ-glutamyl transpeptidase levels remain slightly elevated.

3540 DEFECTIVE REGULATION OF CHEMOTAXIS IN CIRRHOSIS. *(E.)* Maderazo, E. G.; Ward, P. A.; Quintiliani, R. (Hartford Hosp., Connenticut). *J. Lab. Clin. Med.* 85(4):621-630, 1975.

The possibility of a chemotactic defect was investigated in 11 cirrhosis and three hepatitis patients. All the cirrhotic patients had a history of excessive alcohol intake, and presented with muscular wasting, icterus, and ascites. Serum albumin ranged from 2.0-3.1 g% and total bilirubin from 2.9-16.0 mg%. The three hepatitis patients had acute hepatitis believed to be caused, resp., by alcohol, halothane, and methimazole. Serum transaminase levels ranged from 113-1850 U/dl, serum albumin from 3.5-4.4 g%, and total bilirubin from 0.4-12.8 mg%. Neutrophils were obtained by sedimentation of heparinized blood in an equal volume of 6% dextran in phosphate buffered saline, low speed centrifugation, and resuspension in medium 199. Chemotactic assays were performed. Sera were also ultracentrifuged and assayed for chemotactic factor inactivator. For controls, neutrophils and sera of healthy adults were assayed. Two of the cirrhotic sera reduced chemotactic activity by 64% and 90% while control serum caused no fall in activity. Nine of the cirrhotic sera reduced activity 97-99% while alcoholic hepatitis serum reduced it only 17% and control serum produced no inactivation. Serum from a patient with juvenile cirrhosis associated with α-$_1$antitrypsin deficiency showed 36% inactivation, while sera from the halothane and methimazole-induced hepatitis showed little or none. These chemotactic defects were seen only when normal or cirrhotic neutrophils were suspended in the presence of cirrhotic serum. To distinguish between the inhibitory effect of cirrhotic serum on neutrophils as opposed to chemotactic factors, cirrhotic serum was incubated with bacterial chemotactic factor, and then heat-inactivated. Other sera were heat-inactivated first, and then incubated. Using normal neutrophils, it was found that unheated cirrhotic, but not normal serum, would inactivate the chemotactic factor, while the preheated serum lost its inactivating power. Comparison of bacterial chemotactic factor with C3 and C5 fragments, showed that all three factors were inactivated by cirrhotic serum. Ultracentrifugation showed that chemotactic factor inactivator activity appeared between the albumin and cytochrome markers in seven cirrhotic sera, while in three others a small zone of activity was near the IgG marker. In three more, activity peaked only in the upper zone of the gradients. Incubation with zymosan showed generation of significantly less chemotactic activity in cirrhotic than normal sera. It is concluded that in cirrhotic patients there is a chemotactic defect, associated with the serum but not the leukocytes, which is attributable to supernormal levels of chemotactic factor inactivator.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

3565 DISSOLUTION OF STONES IN THE COMMON BILE DUCT WITH BILE-SALT SOLUTIONS. *(E.)* Toouli, J.; Jablonski, P.; Watts, J. M. (Prince Henry's Hosp., Monash Univ., Melbourne, Australia). *Aust. NZ J. Surg.* 44(4):336-340, 1974.

A method is presented for treatment of common bile duct stones discovered after surgical exploration. Retained stones were found in the common bile duct of 14 post-cholecystectomy and two post-cholecystostomy patients treated for acute cholecystitis with removal of the gallbladder stones. Treatment consisted of infusion through the indwelling T-tube or cholecystostomy tube of sterile bile salt solution at 4-6 ml/hr for 10 days. Nine of the patients received an infusion of 200 mM sodium taurocholate, and the other seven received 200 mM sodium cholate. Cholestyramine (4 g) was given p.o. every 6 hr during infusion. If cholangiography revealed improvement after 10 days, treatment was continued, otherwise it was stopped. Stones disappeared in 12 patients, were reduced in size by 1/3 in one, and were unchanged in three. Of these three, one was unable to tolerate the cholestyramine and developed diarrhea; the remaining two were the cholecystostomy patients. In one of these, proper infusion could not be achieved due to leakage around the infusion catheter. In the other the stone may have been of insoluble pigment rather than cholesterol. Side effects included diarrhea (two patients), biliary pain (3), and pyrexia and chills in one. It is concluded that this method is effective and should be attempted before surgical re-exploration is considered.

3566 ENDOSCOPY OF THE BILE DUCT: AN EVALUATION. *(E.)* Leslie, D. (R. Melbourne Hosp., Australia). *Aust. NZ J. Surg.* 44(4):340-342, 1974.

The use of endoscopy in 504 biliary tract operations is reviewed. Of 5 types of instruments (2 types of Sass Wolf, 2 types of Storz, and 1 A.C.M.I. flexible model) the Storz models were the most effective. The A.C.M.I. had poor image and depth of focus, and disorientation occurred as a result of torsion. The Storz models were narrower, more efficient, and had better accessories than the Sass Wolf models. The instrument proved useful in determining patency of the duodenal papilla and in removal of residual stones under visual control. Residual stones were removed in 22% of the patients. Endoscopy was also useful in removal of awkward stones, demonstration of anatomical abnormalities, and discovery of latent pathological lesions such as papillomata, pancreatic carcinoma, fibrosis or edema of the papilla, and cholangitis. Mortality was negligible and in no case did choledochoscopy contribute to cause of death. Wound infection rate was the same as for cholecystectomy with no common bile duct exploration (6%). Operative cholangiography was found to be useful in determining necessity of exploration of the duct. However, 11 of 91 explorations proved to be unnecessary. It is concluded that choledochoscopy is safe, has more to offer than cholangiography, and should be routinely performed after cholangiography.

3567 BONE DISEASE IN INFANTS WITH PROLONGED OBSTRUCTIVE JAUNDICE. *(E.)* Thomas, P. S.; Glasgow, J. F. T. (R. Belfast Hosp. Sick Child., Northern Ireland). *Pediatr. Radiol.* 2(2):125-132, 1974.

Four cases of infants with obstructive jaundice associated with rickets are presented. One case was of intrahepatic cholestasis present from birth, and decreased slowly in severity over 4 weeks without specific treatment. Marked decalcification of the bones was noted 2 weeks after discharge from the hospital. The second case had obstructive jaundice from birth associated with Rhesus isoimmunization. The liver and spleen were enlarged. At 4 months, x-rays showed mild rachitic changes of the wrists and knees. Oral phenobarbitone decreased serum bilirubin level to normal; however, the rachitic changes became more pronounced. Large doses of vitamin D subsequently corrected this and growth became normal. In the third case, jaundice from complete obstruction was noted soon after birth. Laparotomy disclosed extrahepatic biliary atresia. Skeletal x-rays showed lucent zones at the long bone metaphyses and encircling the round bones, presumably due to growth arrest. Vitamin D therapy was begun at 7 weeks of age, but the bony changes were slow to heal and growth remained poor. In the last case, jaundice was noted at 4 weeks of age, and laparotomy disclosed extrahepatic biliary atresia. Rachitic rosary and frontal bossing were noted. Vitamin D therapy was not begun until 13 months of age, and gross limb disease and permanent deformity resulted. Because of the differing etiology of the jaundice in the four infants, it is suggested that reduced bile salts in the intestine may be the major etiological factor in the development of the rickets. Because the severity of the rickets was directly related to the amount of time before vitamin D therapy was begun, it is suggested that infants with jaundice be given prophylactic doses of fat soluble vitamins.

3568 DUODENAL BILE ACIDS AFTER A TEST MEAL. *(E.)* Fausa, O. (Rikshosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(6):567-570, 1974.

Bile acids in duodenal aspirates after test meal stimulation of gallbladder emptying were examined in 12 healthy volunteers (4 women and 8 men, ranging in age from 20-46 yr), using a purified 3α-hydroxysteroid dehydrogenase for the quantitative determination. An average total bile acid concentration of 14.5 μM/ml (range 5.8-39.6) was found. All bile acids were conjugated, the mean ratio of glycine-conjugated to taurine-conjugated bile acids being 3.2. The bile acids were conjugated in the same proportions with glycine and taurine. Expressing the relative proportions of the 3 major bile acids as % of the total, the average value for cholic acid was 40% (range 25-50), chenodeoxycholic 40% (range 30-52), and deoxycholic 20% (range 10-35). These results are in agreement with previously published findings, in which varying methods for gallbladder emptying and for bile acid separation and quantification were used. It is concluded that the method using a purified 3α-hydroxy-steroid dehydrogenase may advantageously be used in the study of duodenal bile acids.

3569 THE INCIDENCE OF SECONDARY COMMON BILE DUCT EXPLORATION. *(E.)* Duff, J. H.; Salvian, A. G.; Finley, R. (Victoria Hosp., London, Canada). *Surg. Gynecol. Obstet.* 139(5):723-725, 1974.

A retrospective analysis was carried out of all secondary common bile duct explorations done at 2 major teaching hospitals in London, Canada during a period of 15 yr to determine the incidence of secondary common bile duct exploration, and to see if the incidence varies with the method of the primary procedure. A total of 112 patients had a secondary common bile duct exploration during the 10-yr period from 1963-1972. At least 1/3 of the patients (46 of 112) already had a common bile duct exploration at the time of cholecystectomy. In these hospitals, 36% of the patients undergoing cholecystectomy have an operative cholangiogram, 13.6% have common duct exploration and 55.2% have cholecystectomy alone. When the group of 112 patients undergoing secondary common bile duct exploration was subdivided according to the method of the initial prodedure, the lowest incidence of secondary common bile duct exploration occurred in patients having operative cholangiograms with cholecystectomy, 0.3-1.0%, and the highest, in those who initially had cholecystectomy and common bile duct exploration, 3.8-5.3%. For cholecystectomy alone, the incidence was 1.2-1.9%. These findings support the selective use of cholangiography with cholecystectomy, although the benefits are small in terms of percent reduction in the incidence of secondary common bile duct exploration. Operative cholangiography may be useful, however, in reducing the number of negative findings at common bile duct exploration performed on the basis of clinical criteria. This is of significant benefit because the frequency of finding stones in the common duct seldom has been above 50%. There was little evidence for the view that performance of a cholangiogram is mandatory with every cholecystectomy. The patients at greatest risk of having retained stones and requiring secondary common bile duct exploration are those who undergo cholecystectomy and common bile exploration as the initial procedure.

3570 CANALICULAR BILE PRODUCTION IN MAN. *(E.)* Prandi, D.; Erlinger, S.; Glasinovic, J. C.; Dumont, M. (INSERM, Beaujon Hosp., Clichy, France). *Eur. J. Clin. Invest.* 5(1):1-6, 1975.

Bile flow, erythritol clearance and bile acid excretion were studied in eight non-icteric patients, aged 47-83 yr, operated upon for gallstone disease without biliary obstruction and in whom T-tubes had been inserted. Bile flow increased from the second (0.27 ml/min) to the seventh (0.50 ml/min) postoperative days and remained stable thereafter. Because the values obtained between the seventh and the 15th postoperative days (average 0.46 ml/min) were not lower and were of the same order of magnitude as those previously reported in the literature for quantitative bile collections, it was assumed that bile collection had been complete. Bile:plasma concentration ratio of erythritol, measured following a single i.v. injection and during constant i.v. infusion of ^{14}C-erythritol, was 0.77. The regression line between erythritol clearance and bile flow had a slope of 0.99 (indicating that increments in clearance were followed by equivalent increments of flow) and an intercept for a zero-clearance of 0.11, suggesting a ductular/ductal secretion of 0.11 ml/min. The relationship between erythritol clearance and bile acid excretion suggested that canalicular bile was formed both of a bile acid-dependent flow (11 µl of water being excreted per µM of bile acid secreted) and a bile acid-independent flow of 0.16 ml/min (or 35% of the average bile flow). These findings indicate that erythritol clearance provides a valid estimate of canalicular bile flow in man and that the three bile fractions previously postulated in animals (canalicular bile acid-dependent, canalicular bile acid-independent and ductular/ductal) may also be present in man.

3571 TREATMENT OF GALLSTONES WITH CHENODEOXYCHOLIC ACID AND PHENOBARBITAL. *(E.)* Coyne, M. J.; Bonorris, G. G.; Chung, A.; Goldstein, L. I.; Lahana, D.; Schoenfield, L. J. (Cedars-Sinai Med. Cent., Los Angeles, Calif.). *N. Engl. J. Med.* 292(12):599-656, 1975.

The effects of treatment with chenodeoxycholic acid (750 mg/day) and/or phenobarbital (180 mg/day) were studied in 22 women and 14 men with asymptomatic radiolucent gallstones and radiologically visualized gallbladders. After 1 yr, chenodeoxycholic acid, phenobarbital and the combination, but not placebo, significantly decreased biliary cholesterol saturation. This effect was significantly greater with chenodeoxycholic acid and the combination than with phenobarbital. Gallstone size decreased more than 50% in nine of 20 patients receiving chenodeoxycholic acid, either alone or combined with phenobarbital, but in no patient receiving only phenobarbital or placebo. Gallstones disappeared completely in patients receiving the combination. Abnormalities in liver-function tests in three of 36 patients, and in five of 16 liver biopsies, occurred with equal frequency in the four treatment groups. Thus, after 1 yr, phenobarbital alone was ineffective in gallstone dissolution. Chenodeoxycholic acid alone or combined with phenobarbital, however, offered a partially effective and safe treatment for asymptomatic radiolucent gallstones.

3572 MITRAL VALVE DEFECTS AND BILIARY DISEASE. *(Ger.)* Koelsch, K. A.; Zemlin, C. (Altstadt Reg. Hosp., Magdeburg, Germany). *Z. Gesamte Inn. Med.* 30(2):51-54, 1975.

Of 184 women, aged 21-84 yr (mean 61.3 yr) who died with a mitral valve defect between 1961 and 1971, 80 (43.5%) had biliary disease. These patients consisted of 76 (41.3%) who either had cholelithiasis or had undergone surgery for it; two with acalculous cholecystitis; and two with cholesteatosis. Of these 184 women, 120 had undergone 1-10 pregnancies. The incidence of biliary disease among these women was only 38.3%, while 26 of the 42 nulliparae (61.9%) had biliary disease. Women who died before the age of 50 generally had the most severe mitral valve defects and the highest incidence of biliary disease, suggesting that there is a correlation between the severity of the heart disease and the incidence of cholelithiasis. This was confirmed by comparing the incidence of biliary disease as a function of the type of mitral valve defect. The incidence of cholelithiasis was highest among women who had damage to other heart valves in addition to the mitral valve (51.1%) and among those with mitral insufficiency (50.0%). Cholelithiasis was also found in three of the five women with defects of the tricuspid, mitral, and aortic valves; two of these three patients had cirrhosis, and the liver was undergoing cirrhotic transformation in the third. Of 21 patients with severe liver disease (cirrhotic transformation, cardiac cirrhosis, or other forms of cirrhosis), 13 (61.8%) had biliary disease. No association was found between biliary disease and obesity or diabetes mellitus in this group of patients.

3573 RACIAL INFLUENCE ON THE INCIDENCE OF BILIARY ATRESIA. *(E.)* Shim, W. K. T.; Kasai, M.; Spence, M. A. (Univ. Hawaii Med. Sch., Honolulu). *Prog. Pediatr. Surg.* 6:53-62, 1974.

Estimates of the incidence of biliary atresia for seven major races in Hawaii were obtained. The rate of biliary atresia in Hawaii differs significantly among some of the groups: 0.6/10,000 births for Caucasians, 0.8 for Japanese, 2.0 for Filipinos, and 3.0 for Chinese. There is a 5-fold difference between the Caucasian and Chinese rates. The incidence of biliary atresia among Japanese in Sendai, Japan, is almost exactly the same as it is for the Japanese of Hawaii. The rate for both Japanese and Caucasians is similar, which is contrary to the impression of some pediatric surgeons. When the incidence of biliary atresia is based on hospital admissions, very disparate and non-comparable figures for Hawaii and Sendai are obtained. The reasons for this difference probably reside in the fact that these figures reflect additional variables, such as referable patterns. When incidences are compared on a geographical basis, the rates are dependent upon the racial composition of the local population under consideration. A conglomerate figure for several races is meaningless, so that racial incidence is probably more accurate in comparing disease rates. Regression analysis demonstrated that father's age, mother's age, father's race, and birth weight are all significant variables and correlate with the incidence of biliary atresia. However, these factors did not account for more than 1% of the variation and leave 99% of the variation in the etiology of biliary atresia still unexplained.

3574 DIAGNOSTIC EVALUATION OF VARIOUS TECHNIQUES FOR EXAMINING THE DUODENUM IN PATIENTS WITH RECURRENT PAIN AFTER CHOLECYSTECTOMY.

(Rus.) Buianov, V. M.; Vorobiev, L. P. (N. I. Pirogov 2nd Med. Inst., Moscow, USSR). *Ter. Arkh.* 46(4):48-53, 1974.

Examination of the duodenum and the papilla of Vater was carried out in 106 patients with recurrent pain after cholecystectomy to reveal a variety of organic and functional changes in the duodenum in patients with postoperative syndromes. Directed roentgenological examination showed that 1/3 of the 98 patients had dyskinesia, and 20 patients had duodenitis. In addition to regular x-ray examination, 36 patients had their duodenum x-rayed in conditions of atropine-induced hypotonia. As a result, pancreatitis was found in 12 patients, papillitis in two, and duodenitis in six; no changes were observed in 16 patients. Duodenoscopy revealed that of the 54 patients examined, 28 had duodenitis; 12, acute or stenotic papillitis; seven indirect signs of the inflammation in the head of the pancreas. It is concluded that 2/3 of the examined patients had functional or morphologic changes in the duodenum and the papilla of Vater. Of the available diagnostic techniques, duodenoscopy appears to be the most effctive in combination with duodenometry and duodenography.

3575 STENOSING LESIONS OF THE BILIARY TREE: EVALUATION WITH ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY (ERC) AND PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY (PTC).

(E.) Geisse, G.; Melson, G. L.; Tedesco, F. J.; Kelly, J. J.; Stanley, R. J. (Washington Univ. Sch. Med., St. Louis, Mo.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):378-385, 1975.

Nine patients with localized or diffuse stenosing lesions of the biliary tree and a tenth patient with a by-passing choledochojejunostomy were evaluated using endoscopic retrograde cholangiography (ERC) and/or percutaneous transhepatic cholangiography (PTC). The patients were premedicated with atropine (0.6 mg, i.m.), meperidine (50 mg, i.m.), diazepam (10-20 mg, i.v.), and a pharyngeal spray containing 2% tetracaine; they were examined with the Olympus duodenofiberscope JF Type B. ERC revealed intra- and extrahepatic narrowing and marked luminal irregularity consistent with sclerosing cholangitis in three patients. In two of these patients, the cholangitis was associated with ulcerative colitis. In a fourth case, ERC demonstrated extensive intermittent narrowing of the intrahepatic duct system highly suggestive of secondary sclerosing cholangitis; open wedge liver biopsy showed marked ascending cholangitis with periductal fibrosis. In another case, ERC showed high-grade stenosis confined to the junction of the left and right hepatic ducts; the diagnosis of primary scirrhous carcinoma was confirmed at surgery. Uncomplicated, discrete, postsurgical extrahepatic strictures were demonstrated in three additional cases; in one of these, PTC was needed to supplement the diagnostic evaluation in that ERC did not show the length of stricture or appearance of the biliary tree proximal to the stricture. In the tenth case, PTS demonstrated stricture at the choledochojejunal anastomosis and a peculiar rectangular filling defect within an hepatic duct proximal to the stricture; the interpretation of a retained portion of surgical stint was confirmed at surgery. When supplemented with the appropriate use of PTC, many lesions of the biliary treat which heretofore were not diagnosable preoperatively can be clearly defined with ERC. These techniques are of value in diagnosis, determination of prognosis, and the provision of visual data on which to plan a surgical approach.

3576 CHOLELITHIASIS IN CHILDREN.

(Ger.) Jenny, P.; Ferel, G.; Herzog, B. (Child. Hosp., Basel, Switzerland). *Helv. Chir. Acta* 41(5/6):757-759, 1974.

Five cases of cholelithiasis in children in the patient material of the Basel Children's Hospital during the 1951-1973 period are reported. The incidence was in agreement with literature data indicating one case out of 7,000 to 12,000 admissions. The patients, four females and one male, were aged 6.5-14 yr at the time of the operation. Spherocytosis with hemolysis was diagnosed in two cases as an underlying disease, and portal hypertension with esophageal varices was found in two other cases. The etiology was obscure in one case. No increased frequency of cholelithiasis was found in any of the respective families. Epigastric pains were found to be the principal symptom of the disease, while colic was infrequent. Cholecystectomy was successful in four cases, and a pea-sized solitary stone was removed by cholecystotomy in another case.

3577 INTERNAL DIAMETER OF THE COMMON BILE DUCT AND ITS SIGNIFICANCE IN EVALUATING THE BILIARY TRACT DURING SURGERY.

(Ger.) Persenico, S. G.; Schamaun, M. (Rhaetian Canton. Reg. Hosp., Chur, Switzerland). *Helv. Chir. Acta* 41(5/6):615-618, 1974.

The internal diameter of the common bile duct was determined in 252 adult patients with diseases of the biliary duct by intraoperative cholangiography, using a new radiomanometric method, to establish relationships between the internal diameter of the common bile duct and the incidence of pathological conditions. The findings indicate that it is impossible to infer any pathological conditions from the internal diameter of the common bile duct in a range of 5 to 11 mm. However, the probability of pathological changes increases with the internal diameter. While the probability of pathological changes is very slim at diameters below 8 mm, it increases to 23.5% at 9 mm, to 40% at 10 mm, and to 57% at 11 mm diameter. Internal diameters greater than 11 mm were found to be always indicative of pathological changes of the common bile duct. The internal diameter of the common bile duct was found to be independent of sex and the duration of the symptoms, while a slight increase in diameter with advancing age was observed.

3578 PRIMARY SCLEROSING CHOLANGITIS. *(Ger.)*

Arma, S.; Fleischer, M.; Fumagalli, I. (B. V. Hosp., Mendrisio, Switzerland). *Helv. Chir. Acta* 41(5/6):699-703, 1974.

Primary sclerosing cholangitis in a 73-yr-old male patient is described. Cachexia, pruritus, mild intermittent obstructive jaundice, and bilirubin levels between 4 and 6 mg% were the first findings. Slight hepatomegalia, considerable thickening of the walls of the gallbladder and of the extrahepatic bile duct, enlarged lymph nodes in the hepatoduodenal ligament, and pronounced collagen proliferation with lymphocyte and plasmocyte infiltration of the gallbladder wall were found during choledochoduodenostomy. Total regression was acheived in a relatively short time following surgery and corticosteroid (betamethasone) therapy.

3579 PRIMARY AND SECONDARY SCLEROSING CHOLANGITIS. *(Ger.)*

Hahnloser, P.; Forrer, P.; Knoblauch, M. (Canton. Hosp., Zurich, Switzerland). *Helv. Chir. Acta* 41(5/6):691-698, 1974.

A case of primary sclerosing cholangitis in a 41-yr-old male patient is reported, and etiological and symptomological problems of primary and secondary sclerosing cholangitis are discussed. Recurrent lymphadenitis and bilateral sclerosis of the hili, axillary lymphadenitis, extrahepatic and intrahepatic sclerosis of the biliary ducts, jaundice, septic temperature, and obstruction of the right hepatic duct justified the diagnosis of primary sclerosing cholangitis against the background of multifocal sclerosis. Unlike secondary sclerosing cholangitis, primary sclerosing cholangitis continues to be of unknown etiology. It is impossible to distinguish between the pure form and that combined with other fibrotic diseases of equally unknown etiology, such as multifocal fibrosis, fibrosing mediastinitis, ulcerative colitis, Crohn's disease, or Riedel's goiter. Intermittent obstructive jaundice with or without septic temperatures is a common feature of primary and secondary sclerosing cholangitis. While secondary forms can be corrected by removal of the biliary duct obstruction, primary forms usually progress into secondary biliary cirrhosis with suppurative hepatitis and coma despite adequate long-term drainage by biliodigestive distulization and long-term steroid and antibiotic therapy.

3580 FLATULENT DYSPEPSIA IN PATIENTS WITH GALLSTONES UNDERGOING CHOLECYSTECTOMY. *(E.)*

Kingston, R. D.; Windsor, C. W. O. (Worcester R. Infirm., England). *Br. J. Surg.* 62(3):231-233, 1975.

The incidence of flatulent dyspepsia and its relation to gallbladder function was studied in 100 consecutive patients (75 women, 25 men, aged 17-80 yr) with gallstones undergoing cholecystectomy. The follow-up was between 3 months and 3 yr. A patient was considered to have flatulent dyspepsia if 3 or more of the following symptoms were present consistently to a moderate or severe degree: repeated belching; feeling full after a normal-sized meal; inability to finish a normal sized meal; abdomen blown out so that clothes need to be loosened; burning discomfort in the epigastrium; burning discomfort in the chest; and vomiting or nausea. A combination of the last 3 symptoms only was not classified as flatulent dyspepsia. Thirty-three percent of patients suffered significant flatulent dyspepsia of whom 80% were cured or improved by operation. Pre- and postoperative gastric emptying times were measured in 15 patients: 5 flatulent dyspeptics who were cured by operation, 5 who were not cured, and 5 patients without symptoms of flatulent dyspepsia. There was no difference in gastric emptying times between patients with flatulent dyspepsia who were cured by operation and those who remained symptomatic. The symptoms of flatulent dyspepsia were correlated with the bacteriological findings of the bile taken from the gallbladder at operation. In the nondyspeptic group equal numbers of patients (13) had infected and noninfected bile. In the dyspeptic patients 8 had infected bile and 5 had sterile bile. Seven of 8 patients cured of the dyspepsia by operation had infected bile, while the bile was sterile in those whose symptoms remained. This suggests that infection within the gallbladder may be a factor in the causation of flatulent dyspepsia. Half of the nondyspeptic patients, however, had infected bile, indicating that it may be a matter of degree and a certain type or level of infection needing to be present before becoming significant in producing flatulent dyspepsia. The concept of a functioning gallbladder emptying infected bile into the duodenum producing an ileus with reflux of bile into the stomach appears to be a very possible cause of flatulent dyspepsia.

3581 PERIBILIARY FAT: A NEW ROENTGENOGRAPHIC FINDING. *(E.)*

Shaub, M. S.; Birnbaum,

W. W.; Meyers, H. I. (Univ. South. California Med. Cent., Los Angeles). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):330-337, 1975.

The roentgenographic appearance of peribiliary fat which is seen in the right upper quadrant in the area of the liver, adjacent to the bile ducts is described and illustrated. Fat adjacent to the bile ducts appeared roentgenographically either as branching or linear lucencies on plain films of the right upper quadrant or as lucencies adjacent to the bile ducts on i.v. cholangiograms or oral cholecystograms. This lucency was best seen adjacent to the common hepatic and the common bile duct. In some of the early cases seen by the authors, the fat caused lucencies which simulated gas to such a degree that it was considered as a primary diagnosis. The patients, however, had no discernible reason to have gas within the biliary tree. The biliary system was examined at numerous autopsies and it became apparent that fat normally occurs around the bile ducts up to their entrance into the liver. The quantity of fat was roughly proportional to the amount of fat present in the remainder of the subject's body. Thus, the findings of upper right quadrant lucencies due to peribiliary fat are seen roentgenographically most frequently in obese individuals. It was found that these lucencies could help in identifying, locating, and measuring the diameter of the common bile duct when it is only faintly visualized on an i.v. cholangiogram or when its anatomical course is atypical. A review of the literature showed no previous description of the roentgenographic appearance of peribiliary fat. It is suggested that the significance of these findings is that branching or linear right upper quadrant lucencies are not necessarily gas within the biliary or portal system but may be due to prominent peribiliary fat.

3582 LIVER AND PANCREAS SCANNING IN EXTRAHEPATIC OBSTRUCTIVE JAUNDICE (WITH SPECIAL REFERENCE TO TUMOURS OF THE BILE AND HEPATIC DUCTS). *(E.)*

Agnew, J. E.; James, O.; Bouchier, I. A. D. (R. Free Hosp., London, England). *Br. J. Radiol.* 48(567):190-199, 1975.

^{198}Au-gold colloid liver scans and ^{75}Se-selenomethionine pancreas scans in 72 patients with extrahepatic obstructive jaundice were assessed by blind marking to determine: 1) if there is a recognizable liver scan appearance in extrahepatic jaundice, whatever the cause; and 2) if combined liver and pancreas scanning can help to distinguish between carcinoma of the bile and hepatic ducts, pancreatic carcinoma, and nonmalignant extrahepatic biliary obstruction. Of the 72 patients, 25 had carcinoma of the bile or hepatic ducts, 30 had carcinoma of the pancreas with obstructive jaundice, and 17 had nonmalignant obstructive jaundice with normal pancreas. Their scans were compared with liver and pancreas scans from 20 control patients and liver scans from 33 patients with diffuse liver disease. Of the liver scans in extrahepatic obstructive jaundice, 56% showed a filling defect in the hilar region of the liver. This was most frequently seen in the most deeply jaundiced patients, and was reported in 80% of patients with a serum bilirubin greater than 15 mg/100 ml. Combined pancreas and liver scans could not always distinguish between different forms of extrahepatic obstructive jaundice. A normal pancreas scan, however, can virtually exclude a pancreatic carcinoma as the cause of obstructive jaundice. A pancreas scan showing severely reduced uptake favors a diagnosis of carcinoma of the pancreas or of the lower end of the common bile duct. A liver scan showing defective left lobe uptake coupled with a pancreas scan showing normal or only moderately reduced uptake suggests the diagnosis of a carcinoma of the hepatic ducts.

3583 ACUTE REVERSIBLE RENAL FAILURE IN PATIENTS WITH ACUTE CHOLECYSTITIS AND CHOLANGITIS.

(E.) Burden, R. P.; Ash, D. V.; Boyd, W. N.; Gray, J. G.; Aber, G. M. (North Staffordshire Med. Inst., Stoke-on-Trent, England). *Q. J. Med.* 44(173):65-77, 1975.

Renal function was assessed in 14 patients with acute cholecystitis and 2 patients with acute cholangitis in order to establish the incidence and nature of the renal involvement in these diseases. The patients (9 women and 7 men) ranged in age from 30-77 yr and none gave a history of renal disease or urinary tract symptoms. All patients were treated with ampicillin (1 g/day, p.o. or i.v.) and parenteral fluids when indicated. Transient elevations in serum bilirubin, alkaline phosphatase, and SGOT were seen in every case, but only 2 patients had elevated serum amylase concentrations. Liver function tests and serum amylases returned to normal limits within 3-15 days. Six patients had no evidence of renal impairment, 4 had modest elevations in their plasma urea and creatinine concentrations, and 6 had acute reversible renal failure; 3 patients in the latter category required peritoneal dialysis. There was no correlation between the initial plasma creatinine and bilirubin concentrations. All patients had transient polymorphonuclear leucocytosis, 4 showed a transient thrombocytosis, and 5 had thrombocytopenia and RBC fragmentation. Plasma fibrogen and serum fibrin degradation products were elevated in all 8 patients in whom they were measured; these concentrations returned to normal limits on recovery. Most blood cultures were negative for bacteria and all mid-stream urine specimens were sterile. Of 5 bile specimens examined, *E. coli* was isolated in 4 and *Klebsiella* was isolated in the 5th. Renal angiography in 2 patients showed arterial narrowing and occlusion with cortical artifacts. There was a high incidence of facial herpes simplex in the patients who developed renal failure. Conservative management of acute renal failure accompanying acute cholecystitis and cholangitis is advisable. In the patients studied, renal failure probably occurred as a result of intravascular coagulation triggered by hypovolemia, bacteremia, or concomitant pancreatitis.

3584 BILE-SALT GLUCURONIDES IN URINE: SHORT COMMUNICATION. *(E.)* Back, P.; Spaczynski, K.; Gerok, W. (Med. Clin., Univ. Freiburg, Germany). *Hoppe Seylers Z. Physiol. Chem.* 355(6):749-752, 1974.

Synthetic sulphate esters of bile acids, after undergoing solvolytic cleavage, were analyzed to determine whether glucuronide binding occurred in the bile acids prior to renal excretion. Bile acids were extracted from 100 ml of urine obtained from a jaundiced patient and analyzed using various procedures involving treatment with β-glucuronidase. The analytical data give evidence that bile acids are excreted into human urine not only as taurine- and/or glycine-conjugated compounds and as sulphate esters of conjugated derivatives, but also as glucuronides of free acids and of conjugated bile acids.

3585 SURGICAL PATHOLOGY OF THE GALLBLADDER AND BILIARY TRACT: RETROSPECTIVE STUDY OF 4363 CASES. *(Fr.)* Rigo, M.; Mosimann, R.; Ryncki, P.; Saegesser, F. (Dept. Surg., Univ. Lausanne, Switzerland). *Helv. Chir. Acta* 41(5/6):533-536, 1974.

GENERAL

3650 PEUTZ-JEGHERS SYNDROME: ITS NATURAL COURSE AND MANAGEMENT. *(E.)* Utsunomiya, J.; Gocho, H.; Miyanaga, T.; Hamaguchi, E.; Kashimure, A.; Aoki, N.; Komatsu, I. (Sch. Med., Tokyo Med. Dent. Univ., Japan). *Johns Hopkins Med. J.* 136(2):71-82, 1975.

A total of 102 patients with Peutz-Jeghers syndrome were part of a follow-up study. The average age at diagnosis differed little between the sexes, 23 yr for males and 26 yr for females. However, the age distribution curve showed a clustering of males at younger ages. The male:female ratio was 1:1.13. Presenting symptoms included obstruction in 42.8% of the cases, abdominal pain in 23.4%, bloody stool in 13.5%, and anal extrusion of the polyp in 7.2%. The remaining 23.4% were diagnosed primarily because of melanin pigmentation. The most serious complication, intussusception, occurred in 105 cases, mostly in the small intestine (95.2% of the cases). Polyps were detected in 195 of the 222 recorded cases (those for which clinical data was available). The polyps occurred throughout the digestive tract, with the exception of the esophagus. Malignant changes of the polyps were histologically confirmed in 28 cases; including 15 examples of early cancer and 11 of advanced cancer. Although a diagnosis of advanced cancer in the Peutz-Jeghers syndrome does not necessarily indicate that it developed in a polyp, it is noted that many instances of advanced cancer in various parts of the gastrointestinal tract occurred in the present series. Melanin spots were located in the lips or perioral region (94.1%), the buccal mucosa (65.8%), and distal portion of the limbs (73.9% in the upper and 62.2% in the lower extremities) with additional spots in other locations in 21.2% of the examined cases. Of the 102 follow-up cases, 36 were known to have died. Of those who died before age 30, 42.9% were due to polyposis; death occurring after age 30 was attributed to neoplastic disease in about 60% of the cases. Affected parents were found in 57 cases. In one case an affected sibling was found, but diagnosis was not established in either parent. Thus the 58 familial cases amounted to 45.7% of the 127 affected individuals whose family histories were ascertained. Conservative treatment is recommended. If operative measures are necessary, injury to intestinal mucosa should be as limited as possible. If intussusception occurs in the small intestine, polypectomy is mandatory. Polyps in the stomach do not usually produce acute complications. Polyps of the large intestine, though rarely causing intussusception, may cause continuous bleeding in which case fiberscopic polypectomy is useful. If the patient is over 30 yr old, and the polyps are numerous, subtotal colectomy with cecoproctostomy may be carried out due to the high risk for cancer. The results of this study allow the conclusion that persons with the Peutz-Jeghers syndrome are at increased risk for cancer development, particularly cancer of the colon.

3651 ABDOMINAL ACTINOMYCOSIS. *(Fr.)* Mousseau, P. A.; Mousseau-Brodu, M. C. (Hotel Dieu, Nantes, France). *J. Chir. (Paris)* 106(6):565-588, 1973.

Case reports are presented for 4 patients with abdominal actinomycosis, and the 124 documented cases which have appeared in the literature since 1850 are reviewed. A 67-yr-old farm woman and a 60-yr-old cook underwent surgery for suspected cancer of the colon. However, examination of material obtained from a right hemicolectomy, performed on the first patient, showed an amyloid mass, 4 cm in diameter, in the cecum and ascending colon. The peritoneum was hypertrophied and fibrous and contained scattered foci of inflammation surrounded by sulfur granules. The second patient underwent extensive resection of the transverse colon and a loop of small intestine adhering to the tumor. On pathological examination, the tumor proved to be a thickened mucosal infiltration 3 cm long. The mesocolon and mesentery contained scattered necrotic abscesses surrounded by sulfur granules; these abscesses had penetrated the walls of the colon and small intestine. Another patient with actinomycosis of the small intestine had suppurating peritonitis due to perforation of a tumor the size of a potato; perforation was due to an ulcerative process. In serosal exudate there was a microabscess surrounded by a dark mass suggestive of *Actinomyces*. All 3 of these patients recovered uneventfully after removal of the lesion and antibiotic therapy. A 40-yr-old farm worker with a mass in the right iliac fossa proved to have an "anthracoid" abscess between the liver and colon at laparotomy. This was shown to result from an *Actinomyces* infection. The patients recovered after drainage of the abscess and antibiotic therapy.

3652 ACUTE NECROTIZING ENTEROCOLITIS IN INFANCY: A REVIEW OF 64 CASES. *(E.)* Santulli, T. V.; Schullinger, J. N.; Heird, W. C.; Gongaware, R. D.; Wigger, J.; Barlow, B.; Blanc, W. A.; Berdon, W. E. (Coll. Physicians Surg., Columbia Univ., New York, N.Y.). *Pediatrics* 55(3):376-387, 1975.

Clinical experience with 64 patients (35 girls and 29 boys) seen over a 20-yr period with acute necrotizing enterocolitis in infancy was reviewed. Of the 64 patients, 47 were born prematurely (73%). Diagnosis was based on tissue examination in 57 and on clinical syndrome, including pneumatosis, in 7. It is suggested that there are different gradations of this disease and that a much larger number of infants are seen and treated before developing the complete syndrome. Three factors are important in the development of the disease: injury to the intestinal mucosa; the presence of intestinal bacteria; and feedings (as a substrate for the bacteria). The importance of stress in the pathogenesis of the disease is confirmed by the high incidence of perinatal complications, particularly hypoxia. It was felt that indirect injury to the mucosa on the basis of selective mesenteric ischemia in response to stress was more important than direct injury to the mucosa from hyperosmolar feedings. Six of 37 patients treated medically survived. Their management included nasogastric decompression, i.v. fluid therapy, attention to acid-base and electrolyte balance, parenteral broad-spectrum antibiotics, frequent physical examination, and roentgenographic studies every 4 hr to detect pneumoperitoneum. Operations were performed on 27 patients; 8 survived. Indications for operation were pneumoperitoneum, peritonitis, and intestinal obstruction. Overall survival rate was 14 of 64 patients (22%). Survival was 16% without and 30% with operation. The preferred procedure is resection of all involved portions of bowel with a proximal enterostomy (chimney) type of side-to-end anastomosis, or resection with double enterostomy when the former is not feasible. The current plan of management requires immediate cessation of oral or gavage feedings, institution of nasogastric tube suction and administration of appropriate i.v. fluids. Parenteral antibiotics are given, usually ampicillin (150 mg/kg/24 hr). Topical antibiotics are administered by gavage at one or two times the parenteral dose of kanamycin or gentamycin/day in 6 divided doses. Low molecular weight dextran 40 is given i.v. in 10% solution, 10 mg/kg every 6 hr for 48 hr. Supine and left side down decubitus x-ray films are taken every 4 to 6 hr to detect unrecognized pneumoperitoneum or peritoneal fluid, and the infant is examined frequently for localized peritonitis. Any of these changes indicates surgery. Of the last 10 patients so treated, only one was operated on and she survived. Of the nine not operated on, four survived.

3653 FACTORS AFFECTING BILE ACID METABOLISM IN CHOLERRHEIC ENTEROPATHY.

(E.) Mitchell, W. D.; Findlay, J. M.; Macrae, R.; Eastwood, M. A.; Anderson, R. (Univ. Dep. Med., Edinburgh, Scotland). *Digestion* 11(1/2):135-146, 1974.

Fecal bile acid excretion and mouth to anus transit time were measured in 10 normal subjects and 9 patients (4 females and 5 males, aged 32-78 yr) with cholerrheic enteropathy. Bacteriological examination of the feces was carried out. All patients had ileal resections of varying lengths and had diarrhea. There was a significant increase in daily fecal weight and total bile acid excretion in feces of patients compared to normal subjects. There was also a marked difference in the pattern of bile acids excreted. Diarrheal patients excreted mainly 3,7-disubstituted (chenodeoxycholic acid) and 3,7,12-trisubstituted (cholic acid) bile acids whereas normal subjects excreted only 3-monosubstituted (lithocholic acid) and 3,12-disubstituted (deoxycholic acid) bile acids. The transit time in patients with ileal resection (mean 36.1 hr) was shorter than controls (mean 54.5 hr.). The concentration of bile acids in the stool from patients with ileal resection diarrhea was 3-4 times more than that for normal individuals, 16.4 *versus* 4.9 mM. There was no significant difference in the type and number of microorganisms occurring in the feces of the two groups. The pH of the fecal homogenate remained constant at pH 7 even after anaerobic incubation for 48 hr, thus explaining why no significant change in bacterial counts were observed after incubation with high concentrations of bile acids. The effect of altering the concentration of sodium taurocholate, sodium glycocholate and sodium taurochenodeoxycholate on the deconjugation and 7α-dehydroxylation of these bile acids by a fecal homogenate from a normal subject was also studied. There was no evidence of inhibition of deconjugation at concentrations as high as 15 mM. However, there was progressive inhibition of 7α-dehydroxylation at 24 and 48 hr with increasing concentration of bile acids, and at 10 mM and above, there was complete inhibition. Deconjugation of bile acid conjugates was normally complete between 6 and 12 hr. It was only after 24 hr that appreciable 7α-dehydroxylation occurred. These results support earlier findings that the major initial reaction in the catabolism of bile salts by intestinal bacteria is hydrolysis of the amide link. It is concluded that the presence of primary bile acids in the stool of patients with ileal resection can be explained by the inhibitory effect of bile acids at concentrations of more than 15 mM. At bile concentrations of less than 15 mM, transit time becomes relevant to 7α-dehydroxylation by fecal microorganisms.

3654 SERUM α-FETOPROTEIN IN PATIENTS WITH NEOPLASMS OF THE GASTROINTESTINAL TRACT.

(E.) McIntire, K. R.; Waldmann, T. A.; Moertel, C. G.; Go, V. L. W. (Natl. Cancer Inst., Bethesda, Md.). *Cancer Res.* 35(4):991-996, 1975.

Serum α-fetoprotein (AFP) levels were measured by a double-antibody radioimmunoassay technique in 580 patients with a variety of malignant and nonmalignant gastrointestinal diseases to determine the incidence of levels elevated above 40 ng/ml. Serum samples from 180 normal adults and 20 normal children (1-10 yr of age) were measured and the AFP levels were all less than 40 ng/ml. Elevated AFP levels were demonstrated in 24% of 45 patients with pancreatic carcinoma, 25% of eight patients with biliary tract carcinoma, 15% of 95 patients with gastric carcinoma, 3% of 191 patients with colorectal carcinoma, and 70% of 73 patients with primary liver carcinoma.

3655 SUBPOPULATIONS OF THYMUS DEPENDENT AND THYMUS INDEPENDENT LYMPHOCYTES IN HUMAN GUT ASSOCIATED LYMPHOID TISSUES.

(E.) Mavligit, G. M.; Jubert, A.; Gutterman, J. U.; Reed, R. C.; Hersh, E. M. (M. D. Anderson Hosp. Tumor Inst., Houston, Texas). *Surg. Gynecol. Obstet.* 140(3):397-400, 1975.

The proportions of thymus independent and thymus dependent cells in the human appendix and terminal portion of the ileum were studied using immunofluorescence and by rosette formation techniques. Lymphoid tissues from the appendix, terminal ileum, and mesenteric lymph nodes were obtained from two patients undergoing subtotal colectomy (one had Gardner's syndrome and the other had multiple familial polyposis). Spontaneous rosette formation with sheep erythrocytes (E-rosettes) was used to determine thymus dependent lymphocytes. Rosette formation with sheep erythrocytes coated with anti-sheep red blood cells antibody and complement (EAC-rosettes) was used to determine thymus independent lymphocytes. Direct immunofluorescence was also used to determine thymus independent lymphocytes. In the first patient, the appendix and terminal ileum both contained substantial numbers of thymus dependent and independent lymphocytes in almost equal proportions. The rosette formation technique showed a higher percentage of thymus independent cells than did the immunofluorescence technique. In the second patient, only the appendix was available for study but it showed both types of lymphocytes. In lymphocytes from all tissues studied, the predominant surface-bound immunoglobulin was IgM. Thus it was shown that both thymus independent and thymus dependent lymphocytes were present in human gut associated lymphoid tissues.
Of 14 patients with esophageal or small-bowel carcinoma, none had elevated serum AFP levels. Only 1% of 154 patients with nonmalignant, nonhepatic gastrointestinal disease had elevations of AFP. There was a significant elevation of AFP in patients with gastrointestinal neoplasia and the incidence of elevation was dependent upon the site of origin. Patients with carcinoma of the pancreas, biliary tract, and stomach had a greater incidence of elevations than those with carcinoma of the colon, esophagus, or small bowel. The authors suggest that serum α-fetoprotein may or may not be a useful marker for early diagnosis of gastrointestinal cancer, but for patients with advanced cancer, it could act as a marker to indicate the extent of the disease.

3656 SECRETORY AND SERUM IgA IN CHILDREN WITH PROTEIN-CALORIE MALNUTRITION.

(E.) Sirisinha, S.; Suskind, R.; Edelman, R.; Asvapaka, C.;

Olson, R. E. (Dep. Microbiol., Fac. Sci., Mahidol Univ., Bangkok, Thailand). *Pediatrics* 55(2):166-170, 1975.

Secretory immunoglobulin A (IgA) levels of children with protein-calorie malnutrition were measured on admission and during dietary treatment. Twenty-four children aged 1-5 yr had either marasmus (7), marasmus-kwashiorkor (9), or kwashiorkor (8). A majority were judged to have bacterial infections by clinical impression, leukocyte counts, chest x-ray, and blood and stool cultures. Normal well nourished children from the same area served as controls. IgG, and secretory IgA concentrations in nasal washings were determined by electroimmunodiffusion. Secretory IgA concentrations were significantly lower (16.1%) than control values (24.3%) and total serum protein, IgG and albumin were slightly reduced. These values remained substantially the same for days 1-70, but values from days 71-84 were not significantly different from control values. There was no correlation between the values and the 3 different clinical states of the children. Serum IgA was significantly higher in the malnourished children at admission than after dietary treatment, but no secretory component was present and no correlation existed between IgA values for serum and nasal washings. It is concluded that protein-calorie malnutrition results in a small but significant deficiency in secretory IgA, but this probably does not account for susceptibility of these children to infection.

3657 HISTOCOMPATIBILITY ANTIGENS AND SOLID MALIGNANT NEOPLASMS. *(E.)* Tarpley, J. L.; Chretien, P. B.; Rogentine, Jr., G. N.; Twomey, P. L.; Dellon, A. L. (Natl. Cancer Inst., Bethesda, Md.). *Arch. Surg.* 110(3):269-271, 1975.

The relation between histocompatibility antigen phenotypes and solid malignant neoplasms was studied in 633 cancer patients and compared with 489 normal controls by human lymphocyte antigen (HL-A) typing. HL-A typing for 21 specificities was performed by standard microcytotoxicity method. HL-A frequencies were compared using chi-square analysis employing 2 x 2 tables. HL-A8 was elevated in patients with squamous cancer, melanoma, and adenocarcinoma, with the highest incidence in those with salivary gland adenocarcinoma (67% as compared to 17% in controls). A threefold increase in HL-A5 occurred in patients with connective tissue sarcomas (28% as compared to 9% in controls). The patients were studied at varying intervals from time of diagnosis and treatment. Antigen frequencies did not vary when analyzed by time of diagnosis or interval after treatment, thus there was no correlation with survival. The results suggested that certain malignant neoplasms are associated with increased frequency of individual HL-A antigens, and this may give clues to cause and genesis for these tumors.

3658 INFLAMMATION OF THE INTESTINAL MUCOSA AND IMMUNOGLOBULIN PRODUCTION. *(Fr.)* Fodor, O.; Dumitrascu, D.; Radu, D.; Dejica, D.; Grigorescu, M. (3rd Med. Clin., Cluj, Rumania). *Ann. Gastroenterol. Hepatol. (Paris)* 10(5):377-387, 1974.

Immunoglobulins were determined quantitatively by radial immunodiffusion in the jejunal contents of 30 patients with chronic nonspecific enteropathies and the density of plasma cells containing the various types of immunoglobulins was studied by using the direct immunofluorescence technique on frozen or paraffin-embedded sections from the rectal mucosa of 18 patients with ulcerative colitis. In chronic nonspecific enteropathies, intraluminal IgA concentrations were significantly decreased in patients whose jejunal contents contained bacteria; this implies that there is a local immune deficiency. Significant decreases in intraluminal IgA concentrations were also detected in patients with inflammatory changes in the jejunal mucosa. Although IgG and IgM levels exhibited considerable individual variation with no apparent pattern, the sum of IgG and IgM concentrations was correlated with IgD and IgA concentrations, indicating that common immune effects were exerted on local immunoglobulins (IgA) and on the serum types (IgG and IgM). The mean serum IgA concentrations were increased in this group of patients, and the highest concentrations of IgA were found in patients with bacteria in the jejunal contents. In patients with ulcerative colitis, all of whom were in remission, the density of plasma cells containing IgA was decreased in the villous mucosa. No IgA was found at the apical pole of glandular cells in severe forms of ulcerative colitis and acute bacillary dysentery. A large number of cells containing IgE were detected in many cases. The number of cells containing IgG, IgM, and IgD was within normal limits.

3659 EFFECT OF LACTOSE-INDUCED DIARRHOEA ON ABSORPTION OF NITROGEN AND FAT. *(E.)* Bowie, M. D. (Dept. Pediatr., Univ. Cape Town, Rondebosch, South Africa). *Arch. Dis. Child.* 50(5):363-366, 1975.

The absorption of fat and the absorption and retention of nitrogen were studied in 20 children with kwashiorkor. Thirteen of the children showed marked variation of stool weight, stool lactic acid content, and stool sugar on being changed from milk to disaccharide-free diet and back again. These children had severe diarrhea while on milk. Lactose malabsorption in this group (nonabsorbers) was confirmed by abnormal lactose tolerance tests and low or absent small intestine mucosal lactase enzyme assay. Seven children (absorbers showed little variation in stool weight and lactic acid content, and satisfactory lactose absorption. Fa absorption was not affected by lactose-induced diarrhe but nitrogen absorption was impaired. In the nonabsorbers, nitrogen absorption dropped significantly upo reintroduction of milk feeds and reccurrence of diarrhea. Mean stool nitrogen during two periods of lactose-induced diarrhea was 1.14 g and 1.38 g/day. Nitrogen retention in these children was unaffected, and it is concluded that milk and milk products should continue to be used in programs to eliminate malnutrition

3660 CLINICAL AND IMMUNOLOGICAL ASPECTS OF PROTIEN-LOSING GASTROENTEROPATHY. *(Ger.)* Asakura, H.; Morishita, T.; Morita, A.; Hibi, T.; Ono, A.; Tsuchiya, M. (Sch. Med., Keio Univ., Tokyo, Japan). *Leber Magen Darm* 4(3):109-116, 1974.

Of 24 patients sith protein-losing enteropathy, confirmed by the Gordon test using ^{131}I-polyvinylpyrrolidone, six had intestinal lymphangiectasia; five multiple nonspecific ulcers of the small intestine; three each, Menetrier's disease and ulcerative colitis; two, constrictive pericarditis; and one each, stomach cancer, lymphoid hyperplasia of the small intestine, polyposis of the colon, neuroblastoma with retroperitoneal metastases, and transitory intestinal protein loss. Total serum protein concentrations ranged from 3.0 to 6.6 g/100 ml and serum albumin values, from 1.6 to 4.3 g/100 ml. A significant negative correlation between serum albumin concentrations and the rate of albumin degradation was found in this group of patients, while significant positive correlations were obtained in 17 patients with chronic liver disease and five with intestinal malabsorption. IgG concentrations were decreased in 16 and IgA concentrations, in 14 of these 24 patients with protein-losing enteropathies; one patient with multiple nonspecific ulcers of the ileum had an IgA level increased to 420 mg/100 ml. About half of the patients had decreased IgM concentrations. A correlation between immunoglobulin levels and immunoglobulin-secreting cell populations in the jejunal mucosa was found in only two of the seven patients investigated. In patients with intestinal lymphangiectasia, there was a decrease in the number of cells secreting all three types of immunoglobulins; the IgG and IgA populations were normal and the number of IgG-secreting cells was slightly increased in one patient with Menetrier's disease. After a patient with nonspecific ulcers of the small intestine and massive protein losses underwent ileal resection, the number of cells secreting IgA decreased significantly while serum albumin and IgG concentrations normalized. The late type of skin reaction occurred in only three of nine patients with the Mantoux test and in only one of eight with the dinitrochlorobenzene test. Lymphocyte cultures were transformed by phytohemagglutinin in three patients with intestinal lymphangiectasia, Menetrier's disease, and ulcers of the small intestine, resp., and T-cell populations proved to be normal in all five patients investigated.

3661 CELL RENEWAL OF GASTRIC MUCOSA IN ZOLLINGER-ELLISON SYNDROME. *(E.)* Castrup, H. J.; Fuchs, K.; Peiper, H. J. (Dep. Gen. Surg., Univ. Gottingen, Germany). *Acta Hepatogastroenterol. (Stuttg.)* 22(1):40-43, 1975.

The growth of the gastric mucosal cells was studied in 3 patients with Zollinger-Ellison syndrome by an *in vitro* autoradiographic method. Biopsies of 11 volunteers without pathological changes of the stomach served as controls. For the *in vitro* autoradiographic investigations the double-labeling technique with ^{3}H-thymidine was used. Quantitation of the different labeled cells and determination of the ^{3}H-index in the proliferation zone of the deeper portion of the gastric pits permitted the calculation of the DNA synthesis phase and the mean generation time. Histological examinations were also done to determine mucosal thickness and mean number of parietal cells/fundic gland. In the 3 patients with Zollinger-Ellison syndrome, the fundic gastric mucosa was thickened with a marked increase of the specific glandular cells. The autoradiographic examination showed a significant increase in proliferation of the stomach epithelial cells; the mean generation time was decreased from 72 hr (controls) to 45 hr (patients). The labeling index was increased from 10% (controls) to 15% (patients). The DNA synthesis, the G_2 phase, and the mitotic time were not changed. The results suggest that in Zollinger-Ellison syndrome, gastrin seems to have a trophic effect not only on the parietal and chief cells, but also on the cells of the surface epithelium of the stomach.

3662 RADIATION ENTERITIS IN CHILDREN: A RETROSPECTIVE REVIEW, CLINICOPATHOLOGIC CORRELATION, AND DIETARY MANAGEMENT. *(E.)* Donaldson, S. S.; Jundt, S.; Ricour, C.; Sarrazin, D.; Lemerle, J.; Schweisguth, O. (Pediatr. Radiother. Serv., Inst. Gustave-Roussy, Villejuif, France). *Cancer* 35(4):1167-1178, 1975.

Clinicopathologic observations and the method of management in 44 children with radiation enteritis were reviewed. All had received whole abdominal irradiation: 42 were treated by cobalt 60 teletherapy and 2 by 250-kV x-rays. Of the 44 children, 25 were given chemotherapy concomitantly with radiotherapy or within 1 month prior to the irradiation. Severe delayed radiation injury with small bowel obstruction occurred within 2 months after irradiation in 5 of 14 long-term survivors. Histologic appearance in the small bowel revealed severe villus blunting, lymphatic dilatation, and moderately dense inflammatory infiltrate. The 5 children were treated with a specific dietary regime free of gluten, free of protein from cow's milk and lactose, low in fat (0.5-1 g/kg/day), and low in residue. The diet was continued for 12-24 months, and gradual replacement to normal diet was well tolerated. The histologic appearance in the small bowel reverted to normal after dietary treatment. The rationale for the diet was that the histologic findings in the patients were suggestive of those seen in malabsorption from other causes; the continuous improvement in each patient suggests that the effects of the diet may be beneficial for radiation enteritis.

3663 TRAVELERS' DIARRHEA AND TOXIGENIC Escherichia coli. *(E.)* Gorbach, S. L; Kean, B. H.; Evans, D. G.; Evans, D. J.; Bessudo, D. (VA Hosp., Sepulveda, Calif.). *N. Engl. J. Med.* 292(18):933-936, 1975.

Travelers' diarrhea in Mexico was studied to determine the role of a heat-labile toxin-producing strain of *Escherichia coli*. A group of 133 US students were studied for 18 days after arriving in Mexico. Diarrhea developed in 29% after a mean time of 13 days. Heat-labile enterotoxin-producing *Escherichia coli* was found in the stools of 72% of sick and 15% of healthy students, none of whom had the pathogen when they entered Mexico. The incubation period was generally 24-48 hr and the carrier state was less than 5 days in 82% of students. *Entamoeba histolytica* was found in 6% of cases of diarrhea, but no salmonella, shigella, or penetrating *Escherichia coli*. The results suggest that approximately 70% of travelers' diarrhea in Mexico is associated with heat-labile toxigenic strains of *Escherichia coli*, and that the major source of contamination is probably the fecal-oral route.

3664 BENIGN FORM OF NECROTIZING ENTEROCOLITIS. *(E.)* Richmond, J. A.; Mikity, V. (USC Med. Cent., Los Angeles, Calif.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):301-306, 1975.

The case histories and radiographic findings of 7 patients with a mild form of neonatal necrotizing enterocolitis are presented. The infants had comparatively mild clinical signs and symptoms related to the gastrointestinal tract; the radiographic findings included bowel dilatation, pneumatosis intestinalis, and portal venous gas. Significant bowel necrosis does not occur in the benign form of necrotizing enterocolitis. The etiology for the benign form of the disease is unknown but may be related to transient intestinal hypoxia; a benign prognosis may be suggested when pneumatosis intestinalis is present without bowel dilatation.

3665 GASTROINTESTINAL HISTOPLASMOSIS, ROENTGENOGRAPHIC, CLINICAL AND PATHOLOGICAL CORRELATION. *(E.)* Lee, K. R.; Lin, F. (Univ. Kansas Med. Cent., Kansas City). *Am. J. Gastroenterol.* 63(3): 255-265, 1975.

Five cases of gastrointestinal histoplasmosis were studied to correlate roentgenographic changes with clinicopathological findings. Physical examinations and barium studies were done on the 5 patients (3 males and 2 females aged 7-65 yr). When the pathological changes were correlated with the roentgenographic barium studies, 6 patterns of gastrointestinal histoplasmosis were identified: malabsorptive (edema, diffuse inflammatory infiltrates and shallow ulcers); ulcerative (larger and deeper ulcers); polypoid (nodular hyperplasia of the lymphoid follicles and dilated villi); granulomatous (intense and diffuse granulomatous infiltrates); tumefactive (large granulomas); compressive (enlarged mediastinal or mesenteric nodes). The clinical and radiological findings are varied, making the diagnosis of gastrointestinal histoplasmosis difficult; thus, it is suggested that histoplasmosis be included in the differential diagnosis of diseases presenting with a malabsorption pattern, gastrointestinal polyposis, ulcerative and granulomatous gastrointestinal diseases, and carcinoma, particularly with coexisting pulmonary lesions.

3666 A GENETIC STUDY OF LACTOSE DIGESTION IN NIGERIAN FAMILIES. *(E.)* Ransome-Kuti, O.; Kretchmer, N.; Johnson, J. D.; Gribble, J. T. (Univ. Coll. Hosp., Lagos, Nigeria). *Gastroenterology* 68 (3):431-436, 1975.

The ability to digest orally administered lactose was studied in 66 people (10 families) representing a number of Nigerian ethnic groups (European, Yoruba, Yoruba-European, Beni, Ibo, and Ibo-Yoruba-European). Samples of capillary blood were taken from fasting subjects at 0, 15, 30, and 60 min after ingestion of lactose (2 g/kg; maximum 100 g), and a rise in the blood glucose above 20 mg/100 ml defined the subject as a lactose digestor. Where both parents were unable to digest lactose, all of the progeny were lactose nondigestors. When one parent was a lactose digestor (European or Yoruba-European) and one a nondigestor, both types of progeny resulted, but the lactose digestors predominated (18 digestors compared to 11 nondigestors). There was no predominance of either sex or any suggestion of sex-linkage found in the study. The authors suggested that the ability to digest lactose was transmitted as an autosomal dominant gene and represents a mutated gene or a polymorphism. The results from this study and others suggest that the lactose nondigestor is homozygous, but it is impossible to determine whether the lactose digestor is heterozygous or homozygous for the genetic characteristic.

3667 LEUKAEMIC INFILTRATION OF THE GASTROINTESTINAL TRACT: AN UNUSUAL CAUSE OF PROTEIN-LOSING ENTEROPATHY. *(E.)* Cockington, R. A. (Adelaide Child. Hosp., Inc., Australia. *Med. J. Aust.* 1(627):103-105, 1975.

A male Caucasian, aged 5 yr and 4 months, with von Recklinghausen's disease and the juvenile type of chronic myeloid leukemia was studied. The patient presented with a 6 month history of lassitude, anorexia, weight loss, recurrent diarrhea, and increasing distension of the abdomen. The clinical signs included minor hepatosplenomegaly, generalized lymphadenopathy, non-specific papular skin eruptions. The differential leukocyte count revealed prominence of blasts and monocytes. Bone marrow showed myeloid hyperplasia and progressive thrombocytopenia. An increase in hemoglobin-F content in red blood cells was noted and persistent hypoproteinemia. Laparotomy showed dilated small bowel with gross granulation and ulceration of the mucosa, several pseudopolyps, and enlarged lymph nodes within the mesentery. Biopsy samples revealed infiltration of the liver, bowel, and lymph with leukemic cells of the myeloid series. Therapy was begun with 6-mercaptopurine after the diagnosis of chronic myeloid leukemia complicated with leukemic infiltration of the bowel was made. Terminally there was gastrointestinal bleeding and autopsy revealed lesions characteristic of chronic myeloid leukemia with infiltration of the gastrointestinal tract and lesions characteristic of von Recklinghausen's neurofibromatosis.

3668 STRUCTURE OF THE GASTRIC MUCOSA IN ACUTE INFECTIOUS NONBACTERIAL GASTROENTERITIS. *(E.)* Widerlite, L.; Trier, J. S.; Blacklow, N. R.; Schreiber, D. S. (Boston Univ. Med. Cent., Massachusetts). *Gastroenterology* 68(3):425-430, 1975.

The morphology of gastric fundal and gastric antral biopsies obtained serially from 15 normal adult male volunteers who ingested an inoculum containing Norwalk agent was studied. Gastric fundal and/or antral biopsies were obtained serially between 24 and 168 hr after administration of the stool filtrate containing Norwalk agent; base line biopsies were obtained prior to the administration of the agent. The biopsies were obtained p. o. with a multipurpose biopsy tube after an overnight fast. Clinical evidence of gastroenteritis with diarrhea and/or nausea and vomiting developed in nine of 15 subjects within 36 hr after the Norwalk agent was given. The other subjects remained asymptomatic. Gastric biopsies from those with normal base line biopsies remained normal during and after clinical illness, while those with mild to moderate gastritis in their base line biopsies showed persistence but no progression of the lesion during illness. Intestinal biopsies from four of the nine symptomatic subjects showed the typical enteritis lesion associated with this illness. Thus the acute infectious nonbacterial gastroenteritis induced by the Norwalk agent was not associated with a histologically detectable gastric mucosal lesion.

3669 ONCOCYTOMA (MITOCHONDRIOMA) OF THE PAROTID GLAND. AN ELECTRON MICROSCOPICAL STUDY. *(E.)* Sun, C. N.; White, H. J.; Thompson, B. W. (VA Hosp., Little Rock, Arkansas). *Arch. Pathol.* 99(4):208-214, 1975.

3744 MORPHOLOGICAL CHANGES IN THE LIVER IN HEPATIC AMOEBIASIS. *(E.)* Ravi, V. V.; Tandon, H. D.; Tandon, B. N. (All-India Inst. Med. Sci., New Delhi). *Indian J. Med. Res.* 62(12):1832-1837, 1974.

A comparative study of morphological changes in the liver was undertaken in 17 patients with amebic liver abscess, 19 patients with non-suppurative hepatic amebiasis and four patients with asymptomatic hepatomegaly. Percutaneous liver biopsy was performed in all cases. Serum transaminases and serum alkaline phosphatase estimations were done, in addition to BSP retention, serum bilirubin, serum proteins, serum cholesterol, and serum total lipids. The indirect hemagglutination test for amebiasis was done in cases of non-suppurative hepatic amebiasis and cases of amebic liver abscess. The most significant changes in the histopathology of the liver away from the abscess site were regenerative changes in the form of increased anisonucleosis and binucleate cells. Kupffer cell hyperplasia, increased lipofuchsin pigment, portal and sinusoidal infiltration and occasional focal areas of necrosis were also seen. In non-suppurative hepatic amebiasis, the changes were mild and comprised aninucleosis and increased lipofuchsin pigment. No significant abnormality was observed in cases of asymptomatic hepatomegaly. Serum alkaline phosphatase was the most frequent abnormality found in the two disease groups. The indirect hemagglutination test for amebiasis was positive in 14 of 16 cases of amebic liver abscess and in 10 of 19 cases of non-suppurative hepatic amebiasis. The results confirmed earlier findings, and it is concluded that the morphological changes in hepatic amebiasis are non-specific. Regenerative reaction is suggested as the cause of hepatomegaly in non-suppurative hepatic amebiasis and for the diffuse hepatomegaly in amebic liver abscess.

3745 MUCOSAL SURFACE INJURY OF JEJUNAL MUCOSA IN PATIENTS WITH GIARDIASIS: AN ELECTRON MICROSCOPIC STUDY. *(E.)* Tandon, B. N.; Puri, B. K.; Gandhi, P. C.; Tewari, S. G. (All-India Inst. Med. Sci., New Delhi). *Indian J. Med. Res.* 62(12): 1838-1842, 1974.

An electron microscopic study of jejunal biopsy was made in 6 patients with *Giardia lamblia* infection to investigate the role of absorptive cell injury in the mechanism of malabsorption in giardiasis. The morphology of the jejunal mucosa was studied both by light and electron microscopy. Adherence of *G. lamblia* to the microvilli with an apparent decrease of the fuzzy coat and formation of large numbers of lamellated bodies was observed in 3 of 6 patients with steatorrhea. The three patients who had no absorptive function derangement did not show mucosal surface abnormalities. Invasion of the mucosa by the parasite was not observed. The mechanical barrier between the nutrients in the lumen and microvilli of the absorptive cells caused by the adherence of *G. lamblia* to the mucosal surface and the destruction of fuzzy coat are suggested as contributory factors to the mechanism of malabsorption syndrome in patients with giardiasis.

3746 HEPATIC BROMSULPHTHALEIN GLUTATHIONE CONJUGATING ENZYME IN AMOEBIC LIVER ABSCESS. *(E.)* Datta, D. V.; Singh, S.; Samanta, A.; Raidu, S.; Nirankari, O. P.; Chhutani, P. N. (Postgrad. Inst. Med. Educ. Res., Chandigarh, India). *Indian J. Med. Res.* 62(12):1897-1901, 1974.

Hepatic glutathione conjugating ability for BSP in affected and unaffected hepatic lobes in patients with amebic liver abscess was studied by a direct micromethod. The enzyme was measured in the affected lobe in 25 patients and in both the affected and unaffected lobe in 5 additional patients. The enzyme activity in the tissue samples from the affected lobe was significantly lower than that in controls (0.035 *versus* 0.120 mg/g liver/10 min), and the activity was not related to the presence of jaundice. Plasma BSP retention showed no significant correlation with hepatic enzyme activity. Liver biospy from affected lobes showed varying degree of necrosis and degeneration of parenchymal cells and chronic inflammatory cells. Unaffected lobes revealed normal enzyme activity and minimal nonspecific inflammatory changes in histology. The results suggest that impairment of hepatic BSP-glutathione conjugation may be a contributory factor in the pathogenesis of high plasma BSP retention in patients with amebic liver abscess. The low enzyme activity in the affected liver tissue may be related to the release of enzyme into circulation following hepatic damage.

GENERAL

Regional Enteritis

3774 INDICES OF GRANULOCYTE ACTIVITY IN INFLAMMATORY BOWEL DISEASE. *(E.)* Kane, S. P.; Hoffbrand, A. V.; Neale, G. (R. Postgrad. Med. Sch., London, England). *Gut* 15(12):953-959, 1974.

A study of vitamin B_{12}-binding proteins and serum lysozyme in an unselected group of 23 patients with ulcerative colitis and 26 with Crohn's disease (aged 18-84 yr) was performed. Three groups of control subjects were used, 12 healthy persons (aged 18-42 yr), 17 patients (aged 20-72 yr) with diarrhea and abdominal pain not due to ulcerative colitis or Crohn's disease, and 10 patients (18-64 yr) with active rheumatoid arthritis. Normal controls had a mean serum vitamin B_{12} level of 423 pg/ml, whereas the 49 patients with inflammatory bowel disease had a mean of 462 pg/ml. This difference was not significant nor were differences in levels between ulcerative colitis and Crohn's disease patients. The 49 patients with inflammatory bowel disease had a mean total B_{12}-binding capacity of 2.85 ng/ml, while the mean in 12 normal subjects was 1.66 ng/ml, a highly significant difference. There was no significant difference between the mean total B_{12}-binding capacity of normal controls or patients with either non-inflammatory bowel disease or with rheumatoid arthritis. No significant difference was noted in total B_{12}-binding capacity between 23 patients with ulcerative colitis and 26 with Crohn's disease. The rise in serum unsaturated vitamin B_{12}-binding capacities and hence in total B_{12}-binding capacities in patients with inflammatory bowel disease appears largely due to a rise in the granulocyte-secreted binders, transcobalamins I and III, with no significant rise in transcobalamin II. The mean values of total B_{12}-binding capacities increase progressively with disease activity. Moreover, in 7 patients studied before and after treatment, there was a significant fall in total B_{12}-binding capacity as the disease remitted. In attempting to correlate total B_{12}-binding capacity with recognized indices of disease activity, no correlation was found with hemoglobin concentration, serum albumin, or ESR. However, there was a just significant correlation between total B_{12}-binding capacity and circulating granulocyte count. The mean serum lysozyme value in 21 patients with inflammatory bowel disease, 6.8 µg/ml, was significantly greater than the mean value of 5.1 µg/ml in 12 normal subjects. These results show that patients with inflammatory bowel disease frequently have raised levels of total serum vitamin B_{12}-binding capacity due primarily to increased concentrations of transcobalamins I and III. While total B_{12}-binding capacity correlated to some extent with disease activity, it correlated poorly with other established indices of disease activity.

3775 A HYPOTHESIS FOR THE PATHOGENESIS OF CROHN'S DISEASE BASED ON AN ULTRASTRUCTURAL STUDY. *(E.)* Cook, M. G.; Turnbull, G. J. (Dep. Exp. Pathol. Cancer Res., Univ. Leeds, England). *Virchows Arch. Pathol. Anat.* 365(4):327-336, 1975.

Sarcoid granuloma, the distinctive feature of Crohn's disease, has been studied in greater detail and in more cases with electron microscopy to assess the relative importance of factors stimulatory to granuloma formation. The tissue samples were taken from

10 patients (aged 16-63 yr) in whom the history of disease ranged from 4 months to 13 yr. The site of disease was the rectum (2), colon and rectum (1), colon (1), jejunum (1), and ileum (5). One had received no treatment. The others were treated with antibiotics alone (3), antibiotic and steroids (3), steroids alone (1), and antibiotics and sulphonamides (2). Two were classified as having very many granulomata, two with many granulomata, one with few granulomata, one with ill-defined granulomata with isolated giant cells, two with granulomata in the nodes only, and two with no granuloma. Results of this study indicate that in many respects the ultrastructure of Crohn's disease confirms the impression of light microscopy that the nonulcerated epithelium which appears normal on light microscopy shows no abnormalities of fine detail either. Nerve bundles are hypertrophied, but show no ultrastructural abnormalities, and neither do any of the cells of the inflammatory infiltrate. These observations apply to all case studies, including the two without granulomata. These latter two did show a proportion of plasma cells in between the low numbers of granlomatous Crohn's disease and the high numbers seen in ulcerative colitis. This may indicate a humoral response perhaps comparable to that in ulcerative colitis where there is evidence of autoimmune activity against the epithelium. The abundance of mast cells previously reported was apparent only in some of the diseased tissues. The endothelial thickening described earlier was not found. The granulomata in Crohn's disease were ultrastructurally similar to those seen in sarcoidosis and also resemble those produced in positive Kveim tests. The granulomata of an individual case of Crohn's disease show a uniform appearance in terms of vacuolation and pinocytosis, even in widely separated parts of the bowel. This, together with the gradation in the state of vacuolation in the series suggests a synchronized sequence of pinocytosis, vacuole formation and lysosomal activity. The pathogenesis of nongranulomatous forms of Crohn's disease is quite unclear, but there may be an autoimmune humoral element. Cell-mediated hypersensitivity probably stimulated by the episodic passage from the gut lumen of an exogenous antigen seems likely to be the important factor in the pathogenesis of granulomatous Crohn's disease.

3776 EXCISIONAL SURGERY WITH ILEOSTOMY FOR CROHN'S COLITIS WITH PARTICULAR REFERENCE TO FACTORS AFFECTING RECURRENCE.

(E.) Steinberg, D. M.; Allan, R. N.; Thompson, H.; Brooke, B. N.; Alexander-Williams, J.; Cooke, W. T. (Gen. Hosp., Birmingham, England). *Gut* 15(11):845-851, 1974.

The excision of the large intestine with ileostomy is reported in 73 patients (40 men and 33 women) with Crohn's colitis who have been followed for at least 9 year since resection. Sixty-four are still alive and all but two of them are in good health. The age range for onset of symptoms in men was 23-67 yr; in women, 11-40 yr. Continuous symptoms of diarrhea, abdominal pain, general malaise, and weight loss were seen in 42, while 29 ran a chronic intermittent course. Two presented with acute fulminating disease. A mean period of 6.1 yr occurred between onset of symptoms and excisional surgery with ileostomy. A previous bowel resection had been performed on 27. In 54 patients the disease involved the total colon and rectum; in seven, the total colon with rectal sparing; in nine, left side only; in one, right side only. A one-stage panproctocolectomy was the treatment for 36, while five had a two-stage procedure. Early in the series, 12 were treated by a temporary ileostomy followed by a panproctocolectomy. Seven had colectomy with ileostomy where the proximal rectum was exteriorized as a mucous fistula and three had a colectomy, ileo-rectal anastomosis and a defuctioning ileostomy. Ten were treated previously by ileo-rectal anastomosis and were submitted to excision of the rectum with ileostomy due to persistent diarrhea, general malaise, and perianal sepsis. The operative mortality rate was 4.1% (3 patients). In the first 4 weeks, 24 experienced ileostomy dysfunction. The commonest site of sepsis was the perianal wound after proctectomy, which occurred in 21 of 64 patients. Late mortality related to the disease was 7.1%, (5 of 70). During the follow-up period 45 (64%) of the 70 patients have been re-admitted on 96 occasions. Twenty-three had evidence of recurrence, 20 in the terminal ileum, 5 diffuse small bowel, 3 jejunal, and 1 gastric. Of these 23, 20 had undergone 26 resections. Four died after operation for recurrent disease. There was no significant difference in the risk of development of recurrence whether the ileum was involved or not. Considering only colonic involvement, those with left-sised disease (6 patients) all suffered recurrence more than 5 yr after surgery, while 15 of 17 with total colonic involvement recurred within 5 yr of ileostomy. The younger group had both an initially higher incidence of recurrence and a higher annual incidence subsequently. There was a trend toward a higher recurrence risk in patients with a shorter length of history before excisional surgery. The risk of recurrence was the same whether the operation was done as a one-stage panproctocolectomy or a multiple-stage procedure. Of the original 73 patients, 64 are still alive, including 19 of the 23 who had recurrent disease. All but one of these 19 are currently in good health. Of the other 45, only one is not well. Of the 64 survivors, 36 take supplements of potassium, iron, and folic acid, and 8 still receive steroid therapy. It is concluded that, unlike patients with ulcerative colitis, excisional surgery with ileostomy for Crohn's disease cannot guarantee a cure, but most patients remain in good health apart from a small group who experience transient episodes of ileostomy dysfunction.

3777 SPLIT ILEOSTOMY IN THE TREATMENT OF CROHN'S DISEASE OF THE COLON.

(E.) Lee, E. (Radcliffe Infirm., Oxford, England). *Ann. R. Coll. Surg. Engl.* 56(2):94-102, 1975.

A modification of the double-barrelled ileostomy is described for the treatment of Crohn's disease of the colon. A more conservative approach is suggested. The inflamed large bowel is defunctioned by an external diversionary ileostomy. Subsequent treatment includes topical and oral corticosteroids for 3 months. The bowel remains at rest for at least 1 yr, unless the disease progresses. If inflammation continues to progress or a complication develops, resection is undertaken as soon as the patient's general condition permits. Split ileostomy has been used to achieve healing, in cases where there is hope of restoring the continuity of the gut without resection after 12-18 months; to facilitate major resection, in patients requiring the operation but in poor general health; and to facilitate limited resection, in patients with diffuse disease one area of which had a complication requiring resection. There are few postoperative complications. Of 69 patients so treated, 22 have come to proctolectomy. Of the 46 treated to achieve healing, 14 have been closed (four of whom suffered recurrences, one died, and nine are well), 22 are awaiting closure, and 10 underwent proctolectomies for progressive disease. Of the 13 who underwent this procedure to facilitate major resection, nine had proctocolectomies, two were closed without resection, and two are awaiting resection. Of the 10 who underwent this procedure to facilitate limited resection, two were closed without resection, one developed a rectovaginal fistula which healed spontaneously, and seven underwent successful limited resections. The surgical technique and course of treat treatment described is effective in improving the patients' general condition and at the same time allowing the option of further treatment.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
amp	ampere
ATP	adenosine triphosphate
Å	angstrom
BSP	sulfobromophthalein
C	degrees centigrade
cal	calories
cc	cubic centimeter
cm	centimeter(s)
dl	deciliter
DNA	deoxyribonucleic acid
ED$_{50}$	median effective dose(s)
EDTA	ethylenediamine tetraacetic acid
e.g.	for example
EEG	electroencephalogram
ESR	erythrocyte sedimentation rate
g	gram(s)
μg	microgram(s)
Hz	Herz
hr	hour(s)
i.m.	intramuscular
i.p.	intraperitoneal
IU	international unit(s)
i.v.	intravenous
kcal	kilocalorie(s)
kg	kilogram(s)
K$_m$	Michaelis constant
LD$_{50}$	median lethal dose(s)
LDH	lactic acid dehydrogenase
m	meter(s)
M	molar; mole(s)
mM	millimolar; millimole(s)
μM	micromolar; micromole(s)
ma	milliampere(s)
mCi, μCi	milli-, microcurie(s)
mEq	milliequivalent(s)
mg	milligram(s)
ml, μl	milli-, microliter(s)
mm	millimeter(s)
mOsm	milliosmolar; milliosmeter(s)
msec	millisecond(s)
mV	millivolt(s)
min	minute(s)
MTD	maximum tolerated dose
NAD	nicotanamide adenine dinucleotide
NADH	reduced nicotanamide adenine dinucleotide
NADP	nicotanamide adenine dinucleotidephosphate
NAPH	reduced nicotanamide adenine dinucleotidephosphate
ng	nanogram (10^{-9})
nm	nanometer(s)
Pa	ambient pressure
PAS	periodic acid — Schiff
pg	picogram (10^{-12})
pgEq	picogram equivalent(s)
p.o.	orally
ppb	parts per billion
ppm	parts per million
r	Roentgen
RBC	red blood cells (erythrocytes), red blood count
resp.	respectively
RNA	ribonucleic acid
s.c.	subcutaneous
sec	second(s)
SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

3785 GROWTH-HORMONE RELEASE-INHIBITING HORMONE IN GASTROINTESTINAL AND PANCREATIC D CELLS.

(E.) Polak, J. M.; Grimelius, L.; Pearse, A. G. E.; Bloom, S. R.; Arimura, A. (R. Postgrad. Med. Sch., London, England). *Lancet* 1(7918):1220-1222, 1975.

To determine whether growth-hormone release-inhibiting hormone (GH-RIH) is present in endocrine cells outside of the hypothalamus, the upper gastrointestinal mucosa and pancreatic D cells of dogs, pigs, and humans were examined for hormone activity using combined immunocytochemical and histological methods. Cells specifically stained for GH-RIH were seen in all areas of the gastrointestinal mucosa examined, being predominantly localized in the midzone of the glands. The hormone-positive cells were lead-hematoxylin positive but negative with the Masson and Grimelius silver-impregnant techniques. GH-RIH cells were also seen in the human pancreatic islets; these cells corresponded to the argyrophil cells stained with the Hellerstrom-Hellman method for D (α_1) cells. The GH-RIH cells were negative for the Grimelius silver method, which stains the glucagon-producing A cells of the pancreas positively. The results suggest that in the gut, the D cell of the Wiesbaden classification is the most likely source of GH-RIH. They also suggest that GH-RIH may play an important role in digestive regulation.

3786 MORPHOLOGICAL INCONSISTENCY IN LIVER CELLS IN CULTURE.

(E.) Okigaki, T.; Quan, S. G. (Pasadena Found Med. Res., Calif.). *Proc. Jpn. Acad.* 50(7):517-520, 1974.

Morphological changes were studied in cultured rat hepatocytes. Livers from three 12-day-old Wistar rats were minced and dissociated with a mixture containing collagenase, hyaluronidase, and trypsin. A primary culture, grown for 2 weeks in Ham's F-12 medium with 10% fetal calf serum, showed a mixture of hepatocyte-like epithelial and non-epithelial cells. The non-epithelial cells were mechanically eliminated with a sharp pin, and a homogenous population of epithelial cells obtained by clonal isolation and/or treatment with hydrocortisone (20 mg/liter) containing medium. The cultures were studied by time lapse cinematography. Typical epithelial cells in early passages were observed to change their morphology in a relatively short period ot time. One line was not epithelial in morphology in later passages, and showed no liver specific response for tyrosine transaminase, but showed a weak positive reaction for tyrosine aminotransferase. This line had been grown in both arginine-free and hydrocortisone-containing media. Although lacking certain liver specific characteristics, it reacted to thioacetamide in the same manner as normal hepatocytes, with swelling and deformation of nucleoli. It is concluded that cultured liver cells can be classified as typical epithelial cells with liver specific characteristics, hepatocyte-derived near- or non-epithelial cells not retaining many characteristics, and non-epithelial non-hepatocytic cells from the beginning of cultivation.

3787 ULTRASTRUCTURE OF THE DEVELOPING FETAL HEPATOCYTE OF Macaca arctoides: A PROPOSED MODEL FOR STUDIES OF FETAL DRUG METABOLISM.

(E.) Quattropani, S. L.; Stenger, V. G.; Dvorchik, B. H. (Milton S. Hershey Med. Cent., Pennsylvania State Univ., Hershey). *Anat. Rec.* 182(1):103-122, 1975.

The ultrastructure of various developmental stages of the fetal hepatocyte was studied in the stumptail monkey *(Macaca arctoides)*. Groups of six to eight females were mated, and pregnancy and gestational age were determined by bimonthly rectal palpations of the uterus. Fetuses were delivered by Caesarian section between 8:15 and 8:45 A.M. at either 80 (midterm) or 160 (nearterm) days gestation. Immediately following delivery, a slice of the anterior medial portion of the right hepatic lobe was taken from the fetus, fixed in glutaraldehyde, and postfixed in osmium tetroxide. Thin sections were stained in uranyl acetate and lead citrate and studied by electron microscopy. Thick sections of the same blocks (0.5-1.0 μ) were stained with methylene blue and azure C and examined by light microscope. Equivalent specimens were also obtained from a 1-week-old monkey and 12 and 16 week human fetuses. At midterm, 50-70% of a given field was hepatocytes, the rest being hemopoietic tissue. The amounts of hemopoietic tissue and smooth endoplasmic reticulum varied with age, the former decreasing and the latter increasing. The smooth endoplasmic reticular elements were concentrated at the edges of the rough endoplasmic reticular stacks in the immature nearterm. By full nearterm there was a pronounced aggregation of smooth elements in the peripheral cytoplasm. Similar aggregates were seen at 1 week postnatal age. It is concluded that fetal monkey hepatocytes have smooth endoplasmic reticulum, which correlates with their ability to metabolize drugs.

3788 ULTRASTRUCTURAL AND CYTOCHEMICAL STUDY OF MUCOUS GRANULES IN SURFACE AND CRYPT CELLS OF RAT GASTRIC MUCOSA.

(E.) Yeomans, N. D. (Anat. Dep. C, Univ. Copenhagen, Denmark). *Biol. Gastroenterol.* 7(4):285-290, 1974.

The composite mucous granules in gastric mucosa surface and crypt cells were studied for frequency of occurrence at particular sites, reactivity for complex carbohydrates, and susceptibility to proteolytic digestion. Tissues from antral and fundic mucosa from 10 Wistar rats were fixed by perfusion with glutaraldehyde. Some were postfixed with osmium tetroxide. The mucosal surface and upper quarter of the crypts and the bottom of the crypts were examined by electron microscopy and 1000 granules counted in each region. Glycoproteins were demonstrated by a modification of the periodic-chromic acid-silver methenamine method, and protein digestion was carried out by incubation with pronase E. Two types of mucous granule profiles were seen in the surface and crypt cells, depending on the method of fixation. When postfixed with osmium, some granules appeared moderately electron dense and homogenous; the rest appeared to have a highly electron dense core surrounded by a moderately dense outer shell. The cores were central or eccentric with a modal diameter of 250 nm; core to granule diameter ratio was about 1:2. When fixed with glutaraldehyde only, the homogenous granules and outer shells of the composite granules appeared obviously extracted. Granules with cores were more common at the mucosal surface and upper parts of the crypts than at the crypt bottoms both in the antrum and in the fundus. The homogenous granules and outer shells of the composite granules gave a strong cytochemical carbohydrate reaction, but the composite granule cores were non-reactive. Proteolytic digestion removed the cores while leaving the outer shells unchanged. It is concluded that composite granules are common at the surface of rat gastric mucosa and contain cores which are probably of protein with little or no carbohydrate.

3789 ULTRASTRUCTURAL LOCALIZATION OF ACTIN-LIKE FILAMENTS IN RAT HEPATOCYTES. *(E.)* French, S. W.; Davies, P. L. (Dep. Pathol., Univ. British Columbia, Vancouver, Canada). *Gastroenterology* 68(4): 765-774, 1975.

The heavy meromyosin binding technique was used to ultrastructurally identify actin-like microfilaments in hepatocytes. Liver and parotid tissue from three Wistar rats was glycerinated and incubated with heavy meromyosin in three experiments. Pieces of tissue (1-2 mm cubes) were placed in standard salt solution containing 50% glycerol. The glycerol concentration was reduced to 25% and after 4-12 hr was replaced by heavy meromyosin for 24 hr. After fixation in glutaraldehyde, tissues were examined by electron microscope. The parotid tissue served as a positive control. Negative controls were not exposed to heavy meromyosin. The effects of ATP and pyrophosphate on heavy meromyosin binding to actin filaments were tested in two experiments by including these substances with the heavy meromyosin during the filament decoration step. Results were similar for both liver and parotid tissues. In glycerated cells not incubated with heavy meromyosin two filament types were observed: a fine interconnecting network of filaments 5.4-5.9 nm in diameter adjacent to the plasma membrane; and straight filaments, single or in bundles, parallel to the plasma membrane and also deep within the cytoplasm. In the heavy meromyosin-incubated liver, the fine filament network appeared much more abundant than in controls; individual filaments were thicker and covered with spikelike extensions. They connected with the plasma membrane, organelles, and each other, and intersected at close to 90° angles. The straight filaments, in contrast, did not bind heavy meromyosin and appeared to be reduced in number after incubation. They ranged from 8-10 nm in diameter. Pyrophosphate inhibited heavy meromyosin decoration incompletely, while ATP caused complete inhibition. The filament network was largely beneath the plasma membrane facing the sinusoid but was also prominent around the bile canaliculus; the distribution corresponded to the polygonal pattern of actin, as demonstrated by smooth muscle binding antibodies. It is concluded that the ectoplasmic microfilament network is actin and is part of the cell's contractile system.

3790 ONTOGENETIC CHANGES IN THE ULTRASTRUCTURE OF RAT HEPATOCYTE ORGANELLES AFTER PRENATAL X-IRRADIATION. *(E.)* Chedid, A.; Nair, V. (Univ. Cincinnati Sch. Med., Ohio). *Radiat. Res.* 62(1):123-132, 1975.

The radiation-induced suppressive effect on enzyme development in the rat hepatocyte was studied with respect to ultrastructural changes in the endoplasmic reticulum. Pregnant Sprague-Dawley rats received 50 r to the pelvic region on the 13th gestation day and were sacrificed on the 15th and 20th gestation days. In a postnatal series, offspring were sacrificed on the day of birth and the fifth postnatal day. Liver specimens from four fetuses or neonates of each time period were cut into 1 mm^3 cubes and examined by electron microscopy. On the 15th gestation day, fetal hepatocytes, in addition to the normal even cytoplasmic distribution of ribosomes, showed large dense polyribosomal aggregates near the nucleus and cell periphery, sometimes with numerous microtubules and dilatation of the rough endoplasmic reticulum. In the 20th gestation day hepatocytes, smooth endoplasmic reticulum failed to appear. By the day of birth, the polyribosomal aggregates were gone, but smooth endoplasmic reticulum still had not appeared, and necrotic hepatocytes were common in the centrilobular area. In the fifth postnatal day the smooth endoplasmic reticulum had appeared. It is concluded that in conjunction with previous findings, lipid peroxidation, membrane alteration, delayed appearance of smooth endoplasmic reticulum, and polyribosomal aggregation may be sequentially linked events after irradiation.

3791 ELECTRON MICROSCOPE AUTORADIOGRAPHIC STUDY OF INTESTINAL ABSORPTION OF DECANOIC AND OCTANOIC ACIDS IN THE RAT. *(E.)* Carlier, H.; Bezard, J. (Inst. Appl. Biol. Nutr. Aliment., Dijon, France). *J. Cell Biol.* 65(2):383-397, 1975.

Intestinal absorption of [^{3}H]octanoic acid and [^{3}H] decanoic acid was investigated in the rat by electron microscope autoradiography. The common duct of the rats was diverted and a loop of the duodenum was cannulated 24 hr later. Tritiated octanoic acid and decanoic acid were introduced into the lumen of each duodenal loop, and uptake was allowed to proceed for various times up to 15 min. The loop was then removed; one part was used to determine the distribution of radioactivity in different lipid fractions, and an autoradiographic study was performed on the other part of the loop. Radioactivity distribution showed that medium chain fatty acids were absorbed in their nonesterified form and that they were absorbed much more rapidly than oleic acid, a long chain fatty acid. Autoradiographic studies indicated that the medium chain fatty acids were taken up in a molecular or aggregate molecular form, left the epithelial cells by way of the lateral plasma membrane, and were next found in the blood capillaries. The results suggest that the Golgi complex does not play an important role in the absorption of unesterified fatty acids, but seems involved only in the transfer of esterified long chain fatty acids.

3792 HISTOLOGICAL CHANGES IN THE INTESTINAL TRACT OF PREGNANT MICE INFECTED WITH COXSACKIEVIRUS B3. *(E.)* Lansdown, A. B. G. (Clin. Res. Cent., Harrow, England). *Experientia* 31(3):327-328, 1975.

The possibility that protein malnutrition in mice infected with coxsackievirus B3 may be sufficient to elicit morphological changes in the intestinal tract leading to an impaired absorption of essential nutrients which are important for normal fetal growth, as well as for maintaining good maternal health, was examined. Mice were inoculated i.m. with 0.3 ml live or heat-inactivated virus suspension on the eighth day of pregnancy and killed by cervical dislocation on the 18th day. Representative segments of liver, pancreas, stomach, duodenum, ileum, cecum, and colon were fixed in phosphate buffered formalin for histological examination. The stomach and upper regions of the intestinal tract of infected animals appeared normal. The ileum, cecum, and upper colon, however, appeared to be dilated and edema of the lamina propria was identified. In the cecum and colon profound edema was present with a marked dilatation of the gut lumen associated with a thinning and distension of the mucosae. Focally the mucosa was reduced to a single layer of cuboidal cells with few mucus-secreting cells and poorly defined basement membrane. The intestinal changes of edema and focal mucosal atrophy are consistent with a short period of protein deficiency. The implications of these intestinal changes upon the state of health of the pregnant mouse or on the development of the fetuses at 18 days gestation are unclear. In view of previously published evidence that the absorptive capacity of the gut is altered only in advanced cases of protein deficiency resulting from several months deprivation, it is unlikely that the early intestinal changes present in these coxsackievirus-infected mice at the stage examined present any appreciable risk to the health of pregnant mice.

3793 THE ULTRASTRUCTURE OF BRUSH BORDER CELLS IN THE INTESTINE OF NINE TO TEN-WEEK-OLD HUMAN EMBRYOS. *(Rus.)* Kovalchuk, V. K. (Kiev Sci. Res. Inst. Infect. Dis., USSR). *Arkh. Anat. Gistol. Embriol.* 67(10):74-77, 1974.

Electron microscope examination of the intestinal mucosa from 9 to 10 week old human embryos revealed a wide range of intracellular differentiation. Deep inside the mucous gland, brush border cells were poorly differentiated: there were few mitochondria with isolated cristae and poorly developed endoplasm and Golgi's cells. The central regions of the supranuclear zone contained finely granular electron-transparent material which looked like the cytoplasmic matrix of continuously cultured cells. As the differentiation proceeded, this material was replaced by the membranes of the endoplasmic system, ribosomes and mitochondria. In the overlying parts of the crypts, there was dense granular cell structures amidst the cytoplasmic structures. The poor differentiation of brush border cells was combined with enzyme deficiency which was manifested by the negative reaction to acid phosphatase. These findings suggest that the surface layer of the intestinal epithelium may develop during early histogenesis and undergo molecular rearrangement after birth.

3794 FUNCTIONAL POLARITY OF THE RAT HEPATOCYTE SURFACE MEMBRANE: ISOLATION AND CHARACTERIZATION OF PLASMA-MEMBRANE SUBFRACTIONS FROM THE BLOOD-SINUSOIDAL, BILE-CANALICULAR AND CONTIGUOUS SURFACES OF THE HEPATOCYTE. *(E.)* Wisher, M. H.; Evans, W. H. (Natl. Inst. Med. Res., London, England). *Biochem. J.* 146(2):375-388, 1975.

The distribution of a hormone-sensitive adenylate cyclase and a range of enzymic, chemical, and morphological properties were examined in 6 purified plasma-membrane subfractions of liver homogenates from fasted Sprague-Dawley rats. The six subfractions were prepared using a combination of differential, rate-zonal, and density-gradient centrifugation. There were 3 vesicular 'light' subfractions of density 1.12-1.13 and 3 'heavy' subfractions of density 1.16-1.18 containing membrane strips and intercellular junctions. All the subfractions contained a basal adenylate cyclase activity. In one of the light subfractions, the highest glucagon-stimulated adenylate cyclase activity was derived from the blood-sinusoidal face of the hepatocyte; unlike the others, this subfraction was contaminated by Golgi components. All of the subfractions also showed high activities of the following plasma-membrane marker enzymes: 5'-nucleotidase, alkaline phosphodiesterase (nucleotide pyrophosphatase), alkaline phosphatase, leucine naphthyl-amidase, and Mg^{2+}-activated ATP. One light subfraction which showed the highest specific activities of these marker enzymes but lacked a glucagon-stimulated adenylate cyclase activity derived from the bile-canalicular face of the hepatocyte. The heavy subfractions generally showed the lowest enzyme activities, were characterized by the presence of desmosomes and gap junctions, and appeared to originate from the continguous faces of the hepatocyte. Polyacrylamide-gel electrophoresis indicated a general similarity in the protein compositions of the 6 subfractions. Differences in the amounts of various protein and glycoprotein bands correlated with differences in morphology, enzymic composition, and sialic acid content. These results, in conjunction with previous plasma-membrane hormone-binding and histochemical data, indicate the existence of functionally discrete plasma-membrane subfractions originating from geographically separated regions of the hepatocyte surface.

ABSORPTION-EXCRETION-TRANSPORT

3806 FERRITIN IRON ABSORPTION IN MAN. *(E.)* Layrisse, M.; Martinez-Torres, C.; Renzy, M.; Leets, I. (Dep. Exp. Med., Venezuelan Inst. Sci. Invest., Caracas). *Blood* 45(5):689-698, 1975.

The effect of vegetable and animal foods on the iron absorption from ferritin was studied in 108 Venezuelan peasants. Following an overnight fast, the subjects ingested ferritin alone or mixed with various foods which had been biosynthetically tagged with radioiron. Blood was drawn 15 days later to determine hematologic characteristics and radioactivity. The geometric mean absorption of ferritin iron in both normal and iron-deficient subjects was 1.9%, the mean absorption ranging from 0.9% in the normal subjects to 2.5% in those with moderate iron deficiency to 5.7% in those with marked iron deficiency. The administration of ferritin with vegetable foods (maize, wheat, soybeans) resulted in lower absorption values than those obtained with the same foods alone. The iron absorption from ferritin was markedly increased when it was administered with meat or liver, but it did not reach the level observed with these foods alone. The mean iron absorption from 1 mg of ferritin iron was 2.3%, while that from 1 mg of ferric chloride was 11.7%. Carrier liver increased the absorption of both substances and carrier maize markedly reduced the absorption of ferric chloride. When ferritin was administered with 100 mg of ascorbic acid, the geometric mean absorption of iron was significantly increased over that seen with ferritin alone. The results indicate that purified ferritin has a very low absorbability and that its absorption is affected by substances which enhance or reduce iron absorption in the same proportion as vegetal iron.

3807 DIFFERENT PATHWAYS FOR HEPATIC UPTAKE OF TAUROCHOLATE AND INDOCYANINE GREEN.

(E.) Paumgartner, G.; Reichen, J. (Dep. Clin. Pharmacol., Univ. Berne, Switzerland). *Experientia* 31(3):265-392, 1975.

To determine whether different pathways exist for the hepatic uptake of bile acids and anionic dyes, the kinetics of the hepatic uptake of taurocholate and indocyanine green were compared in the perfused rat liver. The livers of specific-pathogen-free male Sprague-Dawley rats were perfused *in situ*, during which ^{14}C-labeled taurocholate (75-25,000 nM) and/or indocyanine green (ICG, 60-50,000 nM) was rapidly injected into the portal vein along with ^{99}Tc^{m}-albumin. The total venous outflow was collected and the radioactivity counted. Taurocholate and albumin were distributed in equal spaces and a certain fraction of the taurocholate was removed by the liver. Similar dilution curves were obtained with ICG, which was also distributed in equal spaces with albumin. The initial uptake rate of both taurocholate and ICG increased with the extra-vascular dose in a nonlinear fashion, exhibiting saturation kinetics. Analysis of these data revealed compatibility with Michaelis-Menten kinetics for both anions. The maximal uptake capacity of taurocholate exceeded that of ICG by a factor of 9. The apparent half-saturation constants for the hepatic uptake of taurocholate and ICG were 90.6 and 50.0 nM/g liver, resp. There was no significant competition between taurocholate and ICG for uptake by the hepatocytes. The results suggest that different pathways exist for the transport of bile acids and anionic dyes from the blood into the hepatocyte.

3808 FURTHER STUDIES ON THE ACTION OF PROLACTIN ON FLUID AND ION ABSORPTION BY THE RAT JEJUNUM.

(E.) Mainoya, J. R. (Dep. Zool., Univ. California, Berkeley). *Endocrinology* 96(5):1158-1164, 1975.

The effects of *in vivo* prolactin administration on the *in vitro* absorption of fluid and ions by the rat jejunum were studied. Ovine prolactin was administered s.c. to intact and hypophysectomized male Sprague-Dawley rats. Twenty-four or 48 hr later, the nonfasted animals were anesthetized and everted sacs were prepared from segments I-V of the small intestine. The sacs were filled with Ringer solution containing glucose and placed in metabolic incubators, after which mucosal transport was measured. Prolactin administration significantly stimulated fluid, sodium, potassium, calcium, magnesium, and chloride transport across the everted jejunal sacs, the latter 2 ions being the least affected. Hypophysectomy caused a significant decrease in fluid and sodium absorption which was prevented by prolactin treatment. The effects of prolactin on fluid and sodium absorption were dose-dependent, maximal stimulation resulting from the administration of 1.0-2.0 mg; higher doses failed to elicit a significant response. The stimulatory action of prolactin was inhibited by the simultaneous administration of vasopressin, which when given alone had no effect on intestinal absorption. In the absence of glucose or in the presence of phlorizin, fluid transport was inhibited, the reduction most dramatic in the presence of phlorizin. Fluid transport was also reduced by the application of ouabain or partial replacement of sodium with isotonic choline chloride. These results suggest that the effects of prolactin on intestinal transport may be dependent on the increased movement of sodium.

3809 KINETICS OF Na^{+} UPTAKE AND TRANSCELLULAR TRANSIT BY THE PANCREAS.

(E.) Rossier, M.; Rothman, S. S. (Dep. Physiol., Univ. California, San Francisco). *Am. J. Physiol.* 228(4):1199-1205, 1975.

The kinetics of Na^{+} uptake and transcellular transit by pancreatic tissue was studied to determine the model for tissue uptake of the molecule. ^{22}Na uptake into strips of rabbit pancreas was measured for up to 10 min. The uptake curve was characterized by the presence of 2 plateaus separated by an inflexion point; a 1st plateau was observed between 1 and 3 min; between 3 and 4 min the slope of the uptake curve increased again; it finally decreased to a new and higher steady-state uptake between 4 and 6 min. The data suggest that the 1st part of the uptake curve (0-3 min) represents uptake into the cells, and the 2nd part (3-10 min) represents the sum of "quasi" steady-state cellular uptake and of the equilibration of the ductal compartment in series with the cells. A delay of 2.5-3.25 min elapsed between the filling of cellular and ductal compartments, which appeared to be of intracellular origin (restricted Na^{+} diffusion within the cytoplasm and an intracellular Na^{+} gradient). Based on that model, the transit time for Na^{+} across the whole organ was expected to be 3-4 min and was found to be 3.5 min when studied *in vitro*. The transepithelial transit of Na^{+} appeared to account for most of that time. The data indicate that a substantial delay exists between the filling of the cells and the ducts; thus, tissue uptake may be described as the sum of an exponential and a sigmoid function.

3810 EFFECT OF A COMBINED THIAMINE AND RIBOFLAVIN DEFICIENCY ON INTESTINAL ABSORPTION OF ESSENTIAL AMINO ACIDS.

(Fr.) Wellers, G.; Chevan, J. (Unit. Inform. Biomed. Res., Paris, France). *Ann. Nutr. Alim.* 28(1):49-63, 1974.

Male Wistar rats were fed a diet containing all 10 essential amino acids plus other essential nutrients but deficient in thiamine and riboflavin. After 20 days, the rats were deprived of all amino acids, but glycine and L-glutamic acid were added to the diet. Three days later, the rats were fasted for 24 hr and a mixture containing all previous nutrients was instilled into their stomachs. After 6 hr, the animals were sacrificed and the amino acid levels in the intestinal contents, blood and gastrointestinal tissues were determined by microbiological assays. Thiamine-deficient rats absorbed arginine at a normal rate, but the other nine essential amino acids were absorbed more slowly than normal. A riboflavin deficiency increased the absorption rate for all amino acids but tryptophan. When rats were deficient in both thiamine and riboflavin, the absorption of histamine, leucine, lysine, methionine, phenylalanine, threonine, and valine were decreased, while arginine, isoleucine, and tryptophan were absorbed at normal rates. Disorders in amino acid absorption in vitamin-deficient rats may be the primary cause of signs of disorders in protein metabolism (weight loss, anorexia) that were observed.

3811 LIVER UPTAKE OF AMINO ACIDS AND CARBOHYDRATES DURING A SINGLE CIRCULATORY PASSAGE. *(E.)* Pardridge, W. M.; Jefferson, L. S. (Milton S. Hershey Med. Cent., Hershey, Pa.). *Am. J. Physiol.* 228(4):1155-1161, 1975.

The uptake of ^{14}C-labeled amino acids and carbohydrates by rat liver following rapid injection into the portal vein was measured using tritiated water as an internal standard; the applicability of this technique (Oldendorf technique) to the study of liver transport systems was then judged. A 0.25 ml bolus of buffered Ringers solution containing 1-2 μCi of the ^{14}C-labeled test substance 3-6 μCi of tritium-labeled water (^{3}HOH) was administered by rapid portal injection into anesthetized male Sprague-Dawley rats. Circulation was terminated after a single passage of the bolus through the hepatic microvasculature and the tissue was immediately macerated, solubilized, and subjected to liquid scintillation counting. Liver uptake indices (LUI) were calculated from the ratio of ^{14}C to ^{3}H in the liver tissue relative to this ratio in the injection mixture. The LUI's of sucrose, inulin, D-mannitol, D-glucose, and L-glucose were 24.3%, 27.7%, 80.2%, 96.8%, and 26.7%, resp.; the LUI for cholic acid was 127.1%. Among the 18 amino acids tested, the LUI's were highest for the acidic compounds (e.g., L-aspartic acid, 100%, and L-glutamic acid, 86.4%) and lowest for the more basic compounds (e.g., L-arginine, 37.4%, and L-lysine, 31.4%). Stereospecificity for glucose and alanine uptake, saturation kinetics for glutamic acid (K_m = 4.8 mM) and aspartic acid (K_m = 2.7 mM), and cross-inhibition among uptake of the various amino acids were observed. The data confirm the applicability of the Oldendorf technique, which was originally developed for studies of amino acid uptake into the brain, for the characterization of transport systems in the liver.

3812 EFFECTS OF CHRONIC ETHANOL ADMINISTRATION ON INTESTINAL ABSORPTION IN MAN IN THE ABSENCE OF NUTRITIONAL DEFICIENCY. *(E.)* Lindenbaum, J.; Lieber, C. S. (Harlem Hosp. Cent., New York, N.Y.). *Ann. N.Y. Acad. Sci.* 252:228-234, 1975.

The effects of chronic alcohol administration on intestinal absorption in man was studied under controlled metabolic ward conditions to determine whether ethanol alone, in the absence of associated nutritional deficiency, causes impairment of small bowel function. Asymptomatic middle-aged male volunteers with histories of chronic alcoholism were given 173-253 g/day of ethanol (46-66% of the total caloric intake) along with vitamin supplementation. Vitamin B_{12} absorption was studied by the urinary excretion method of Schilling following the oral administration of ^{57}Co-cyanocobalamin (0.75 μg) with intrinsic factor concentrate. The excretion of urinary xylose and fecal fat were also determined following the oral or i.v. administration of D-xylose. In 6 subjects, the excretion of B_{12} was reduced during ethanol administration compared with periods of abstinence (control); no depression in vitamin B_{12} absorption was seen in the other 2 subjects, both of whom received the smallest amount of ethanol. The concomitant administration of pancreatic extract did not improve B_{12} absorption during ethanol administration. Urinary xylose and serum xylose increased during ethanol administration and fecal fat excretion was reduced. The absorption of xylose and fat was not inhibited by alcohol administration. The results indicate that chronic ethanol administration results in impaired B_{12} absorption in man despite adequate nutrient intake.

3813 PASSAGE OF PARTICLES THROUGH THE WALL OF THE GASTROINTESTINAL TRACT. *(E.)* Volkheimer, G. (no affil.). *Environ. Health Perspect.* 9:215-225, 1974.

The persorption of macrocorpuscular particles through the wall of the gastrointestinal tract is discussed in terms of mechanisms, rate, and the elimination, phagocytosis, enzymatic degradation, and deposition of persorbed particles. Persorption of particles in the micrometer size range is possible wherever the intestinal mucosa is covered by a single layer of epithelium. Primary transportation of persorbed particles from the digestive tract may take place in the chyle and *via* the portal circulation. The persorbed particles are found between the cells of the epithelial layer, in the subepithelial region of the mucosa, and within the lumen of lymph and blood vessels. The rate of persorption depends on factors such as the age of the subject, quantity of particles supplied, and the muscular activity of the intestine; the rate increases during deep physiological sleep and under the influence of cigarette smoking, caffeine, and prostigmine, and decreases during barbiturate sleep. Persorbed particles may be eliminated in the urine, bile, and milk (in lactating women), and have been observed to pass into the peritoneal cavity and cerebrospinal fluid; extravasation from the vessels in the pulmonary alveoli and transplacental passage have also been confirmed. Phagocytosis by micro- and macrophages was observed in the peritoneal cavity and spleen, and enzymatic degradation of starch granules in the body fluids was demonstrated. Finally, after long-term oral administration, deposition of embolized starch granules and other persorbed particles in the lumen of the smallest vessels has been noted.

3814 MEASUREMENT OF SUGAR ABSORPTION DURING DIGESTION OF CORNSTARCH IN SWINE. *(Fr.)* Rerat, A.; Aumaitre, A.; Vaissade, P.; Vaugelade, P. (Lab. Nutritional Physiol., INRA, Jouy-en-Josas, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 279(10):831-834, 1974.

Glucose absorption during cornstarch digestion was measured quantitatively in 4 swine fitted with permanent cannulas in the portal vein and the anterior vena cava. Blood volumes were continuously recorded with electromagnetic flow meters. Experimental diets containing 150g protein, vitamins, minerals, and 400-1200g cornstarch were fed after 16 or 22 hr fasts, and blood glucose levels were monitored from 30 min before to 8 hr after meals. In spite of large variations in blood flow, the quantities of glucose absorbed were very consistent. Absolute quantities of glucose absorbed were directly proportional to the amount of cornstarch fed, but were relatively higher when smaller portions were ingested. The digestion time was very long and may be as long as 22-29 hr when large quantities of cornstarch are fed. This is in marked contrast to the absorption of amino acids after digestion of proteins, which is almost complete after 8 hr.

3815 THE INFLUENCE OF GLUCAGON ON JEJUNAL ABSORPTION OF GLUCOSE, WATER AND ELECTROLYTES IN MAN. *(Ger.)* Gottesburen, H.; Leising, H.; Menge, H.; Lorenz-Meyer, H.; Riecken, E. O. (Med. Clin., Univ. Marburg/Lahn, Germany). *Klin. Wochenschr.* 52(19):926-929, 1974.

The influence of glucagon on the resorption of glucose, water, sodium and potassium was studied by means of the segmental small-intestinal perfusion method with a three-channelled needle in the upper jejunum in three groups of subjects. These included healthy adults; eight maturity-onset diabetics with reduced insulin secretion after glucagon dose; and six patients with juvenile diabetes mellitus who required insulin. After measuring resorption over two 30-min periods the test subjects received 1 mg i.v. of glucagon and the resorption was determined during four 15 min periods. After glucagon administration in all three groups there was an increase of short duration in glucose absorption. This was more pronounced in the diabetics than in the healthy subjects. Subsequently a significant decrease of glucose absorption took place. Sodium and water uptake were reduced by glucagon administration; in all three groups there was a transient secretion of potassium into the intestinal lumen. These results, obtained after application of pharmacological doses, do not show clearly whether the demonstrated changes of resorption result directly from glucagon or from regulatory processes.

3816 EFFECTS OF BOVINE GROWTH HORMONE, HUMAN PLACENTAL LACTOGEN AND OVINE PROLACTIN ON INTESTINAL FLUID AND ION TRANSPORT IN THE RAT. *(E.)* Mainoya, J. R. (Dep. Zool., Univ. California, Berkeley). *Endocrinology* 96(5):1165-1170, 1975.

The influence of bovine growth hormone and human placental lactogen on intestinal absorption was compared with that of ovine prolactin. Normal and hypophysectomized adult male Sprague-Dawley rats were anesthesized and everted intestinal sacs were prepared from segments III and IV of the jejunum and from the entire colon. The sacs were filled with Ringer solution containing glucose and were placed in metabolic incubators; after incubation, mucosal transport was measured. One mg of bovine growth hormone, ovine prolactin, and/or purified human placental lactogen was injected s.c. 24 or 48 hr before surgery. Administration of each of these hormones resulted in increased fluid and electrolyte transport by the intestinal mucosa. Hypophysectomy produced a fall in fluid and ion absorption in the jejunum, but these changes were prevented by growth hormone administration. Bovine growth hormone and ovine prolactin produced essentially similar effects in intact rats: significant increases in fluid, sodium, and calcium transport in the duodenum; significant increases in fluid, sodium, and potassium transport in the jejunum; and significant increases in sodium, chloride, potassium, and calcium transport in the ileum. Growth hormone also significantly increased the transport of fluid, sodium, and chloride in the colon. Treatment of hypophysectomized rats with human placental lactogen enhanced fluid and ion transport in the jejunum but failed to restore normal potassium transport in the ileum and colon. The results suggest that growth hormone and human placental lactogen affect jejunal water and electrolyte transport in the same manner as does prolactin, possibly by influencing active ion transport.

3817 EFFECTS OF GASTROINTESTINAL HORMONES ON ADENYLATE CYCLASE ACTIVITY IN HUMAN JEJUNAL MUCOSA. *(E.)* Klaeveman, H. L.; Conlon, T. P.; Levy, A. G.; Gardner, J. D. (Natl. Inst. Arthritis, Metab. Dig. Dis., Bethesda, Md.). *Gastroenterology* 68(4):667-675, 1975.

The effects of various polypeptide hormones on the adenylate cyclase activity in the human small intestinal mucosa were investigated to determine the mechanism by which such hormones alter the intestinal transport of salt and water. Peroral small intestinal biopsy specimens were obtained from 19 normal subjects of both sexes. Adenylate cyclase activity in the homogenized samples were determined by measuring the formation of ^{32}P-labeled cyclic AMP from (α^{32}P)ATP in the presence of reaction mixtures containing the various hormones. Vasoactive intestinal polypeptide (VIP) and prostaglandin E_1 (PGE$_1$) activated adenylate cyclase at concentrations of 10^{-7} M, maximal stimulation occurring at concentrations of 10^{-4} M; the effects of these agents were additive. Neither glucagon nor secretin stimulated adenylate cyclase or altered the stimulation produced by VIP or PGE$_1$. Gastrin, cholecystokinin-octapeptide, pentagastrin, human calcitonin, and salmon calcitonin were also incapable of activating adenylate cyclase or altering the stimulating activity of PGE$_1$ or VIP. Several guanyl nucleotides, including guanosine monophosphate, guanosine diphosphate, guanosine triphosphate, and 5'-guanylyl imidodiphosphate, significantly increased basal adenylate cyclase activity but did not alter the effects of PGE_1 or VIP. Several other nucleotide triphosphates (xanthosine triphosphate, inosine triphosphate, cytidine triposphate, uridine triphosphate) did not alter adenylate cyclase activity. These data suggest that VIP and PGE_1 act at functionally distinct sites and that the other polypeptide hormones tested do not interact with the receptors with which VIP and PGE_1 combine to increase adenylate cyclase activity.

3818 STUDIES ON THE METABOLISM OF DIMETHYLNITROSAMINE IN THE RAT. I. EFFECT OF DOSE, ROUTE OF ADMINISTRATION AND SEX. *(E.)* Phillips, J. C.; Lake, B. G.; Heading, C. E.; Gangolli, S. D.; Lloyd, A. G. (Br. Ind. Biol. Res. Assoc., Carshalton, Surrey, England). *Food Cosmet. Toxicol.* 13(2): 203-209, 1975.

Some of the factors affecting the metabolism of dimethylnitrosamine (DMN) in the rat were investigated. ^{14}C-DMN (0.2 ml/100 g) was administered i.p., s.c., i.v. and *via* oral intubation to mature and immature male and female specific-pathogen-free Wistar rats. The excretion of $^{14}CO_2$ was monitored. In other experiments, ^{14}C-DMN was injected s.c. or into the stomachs of pylorus-ligated rats and the absorption of ^{14}C-DMN from the stomach and small intestine was studied. Exhalation of unchanged ^{14}C-DMN accounted for less than 0.4% of the injected dose in the first experiment; the maximum rate of $^{14}CO_2$ production occurred between hr 1 and 4, less than 3% of the injected dose being exhaled between 6 and 24 hr. The maximum rate of $^{14}CO_2$ production was related to dose in both males and females, and the maximum rate of production was significantly lower in mature than immature animals. $^{14}CO_2$ production and the amount of ^{14}C excreted in the urine were similar for all p.o. administration but was significantly lower after p.o. administration. In the pylorus-ligated animals, the maximum rate of $^{14}CO_2$ production and the percentage $^{14}CO_2$ produced in 7 hr were only 45% of the control values. The disappearance of ^{14}C-DMN from the stomach was considerably smaller than from the small intestine, and absorption from the stomach, but not the small intestine, was significantly more rapid in starved than in fed rats. The percentage of ^{14}C remaining in the stomach did not appear to depend on the initial concentration of DMN. The kinetics of the disappearance of radioactivity from the small intestine varied with the intraluminal concentration of ^{14}C-DMN, following a monoexponential curve at very low concentrations and a biexponential curve at higher concentrations. The results suggest that the lower rate of DMN metabolism after oral administration is probably due to slower absorption of this compound from the stomach.

3819 ACTIVE AMINO-ACID AND SUGAR UPTAKE BY GALL BLADDER EPITHELIUM IN DOG, GUINEA-PIG AND MAN. *(E.)* Mirkovitch, V.; Sepulveda, F. V.; Menge, H.; Robinson, J. W. L. (Canton. Hosp., Lausanne, Switzerland). *Pflugers Arch.* 355(4):319-330, 1975.

The *in vitro* uptake of various sugars and amino acids by slices of canine gallbladder mucosa was studied. Samples of gallbladder and common bile duct from adult mongrel dogs, rabbits, guinea-pigs, and human beings were incubated in media containing ^{14}C-labeled substrates, and tissue uptake of radioactivity was determined by liquid scintillation counting. To determine the effect of bile retention on the transport capacity of the canine gallbladder mucosa, the common bile duct was ligated just proximal to the papilla vateri, and the gallbladder and bile duct were excised for examination 2 weeks later. The canine gallbladder was able to accumulate amino acids and sugars against considerable concentration gradients across the luminal membrane of the cell; the epithelium of the common bile duct also absorbed these compounds. The transport systems were sodium-dependent, saturable, and inhibited by ouabain and metabolic poisons (2,4-dinitrophenol and iodoacetic acid). Glycine was preferentially transported across the canine gallbladder from the mucosa to the serosa, but the net flux was small. Concentrative uptake also occurred in the guinea-pig and human gallbladders but appeared to be practically nonexistent in rabbit tissue. The gallbladder epithelium proved to be remarkably resistant to anoxia, and was able to concentrate amino acids and sugars, although to a significantly reduced extent, 2 weeks after obstruction of the common bile duct. The results indicate that the centraluminal membrane of the epithelial cell might be relatively impermeable to glycine and suggest a close similarity between the transport mechanism situated in the luminal membrane of the gallbladder and the proximal tubular cell of the kidney.

MOTILITY

3861 EFFECT OF ISCHEMIC ANOXIA ON MYOELECTRICAL AND MECHANICAL ACTIVITY OF THE TOTALLY ISOLATED CANINE STOMACH. *(E.)* Kowalewski, K.; Zajec, S.; Kolodej, A. (Surg.-Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Surg. Gynecol. Obstet.* 140(2):187-192, 1975.

Electrical and mechanical activities were recorded from the totally isolated canine stomach perfused with homologous blood of a living oxygenator-supported dog. Stagnant ischemic anoxia was induced by closing inflow and outflow blood from the isolated organ for various periods up to 4 hr. Recording of electrical and mechanical activity was performed prior to, during, and after the anoxic periods. After a given period of time, blood was recirculated for 10 min and pentagastrin (5 μg) was injected into the gastric artery. Ischemia induced first low frequency electrical control activity, and it altered the direction of conduction and phase lag of control activity. Contractions, if present prior to ischemia, were abolished after 10-20 min of circulatory arrest. No signals were recorded from electrically active areas of the stomach after 30-50 min of ischemia. After up to 3 hr of anoxia, stomachs showed recordable electrical activity when perfused for 10 min with homologous blood and essentially normal electrical control activity and mechanical activity 10 min after pentagastrin injection. After 3.5-4 hr of anoxia, recirculation of blood and pentagastrin had no effect on electrical and mechanical activity of the gastric musculature. That *ex vivo* canine stomachs can tolerate 3 hr of stagnant ischemia suggests that metabolic function in the smooth muscle cells, responsible for the periodic oscillations in potential, is not irreversibly damaged after this period of ischemia. The response to pentagastrin indicates that functional integrity of the intramural plexus was not destroyed by 3 hr of anoxia and that the nerve plexus layers were still able to synthesize and release acetylcholine.

3862 GASTROESOPHAGEAL DYNAMICS DURING IMMERSION IN WATER TO THE NECK. *(E.)* Johnson, L. F.; Lin, Y. C.; Hong, S. K. (Tripler Army Med. Cent., Honolulu, Hawaii). *J. Appl. Physiol.* 38(3):449-454, 1975.

The gastroesophageal pressure gradient, distal esophageal sphincter pressure, and the gastroesophageal pH gradient were studied in man during immersion to the neck in water, and standing in air with and without abdominal compression. An esophageal pressure probe and pH electrode were passed into the esophagus of five subjects while standing in air. The catheter assembly was advanced in 1 cm increments until all gauges had traversed the distal esophageal sphincter and entered the stomach. The instrument was then withdrawn slowly until the proximal pressure gauge had entered the hypopharynx. During the measurements the subject was encouraged not to swallow. Identical procedures were repeated while the subject was standing in water up to the neck, and was standing in air with a gastric pressure of 20 mm Hg created by a thigh blood pressure cuff around the abdomen. While standing in air, gastric pressure averaged 4.6 mm Hg while the esophageal sphincter pressure was 19.4 mm Hg. The gastroesophageal pressure gradient was 58 mm Hg. During immersion in water, gastric pressure increased to nearly 20 mm Hg and esophageal sphincter to about 32 mm Hg. Esophageal pressure was about 5 mm Hg higher than the corresponding in air measurements, and the point of lowest pressure shifted proximally. While standing in air with abdominal compression, gastric and sphincter pressures were similar to those in immersed subjects, but esophageal pressure was midway between values in immersed subjects and in air subjects. The pH abruptly changed from nearly neutral in the esophagus to strongly acidic as the catheter traversed the sphincter. The location where the pH had been 6 shifted 4 cm proximally during immersion. The esophagus shortened in length between the cricopharyngeus and the upper limit of the sphincter by 11% during immersion and 9.7% during abdominal compression in air. These two values did not differ significantly from each other. Although no evidence of reflux was found, it is suggested that immersion predisposes to gastric reflux in those with low sphincter tone.

3863 EFFECTS OF CAERULEIN ON THE ISOLATED HUMAN ILEUM. *(E.)* del Tacca, M.; Soldani, G.; Crema, A. (Dep. Pharmacol. Univ. Pisa, Italy). *Rend. Gastroenterol.* 6(3):165-167, 1974.

The effects of cerulein on the human intestine *in vitro* was studied using longitudinal strips removed during surgical operations from patients of both sexes. Before beginning the experiments, the preparation was left standing for about 120 min, by which time spontaneous activity had developed; at this time the effectiveness of transmural stimulation was determined with trains of pulses of 1 μsec duration at a frequency of 10/sec lasting for 30 sec. Cerulein produced a pronounced and sustained contraction of the longitudinal muscle, which relaxed after washing. Tachyphylaxis readily occurred. The threshold concentration differed from one organ to another, but in all the experiments cerulein was used at 1×10^{-8} g/ml. In the presence of atropine (5×10^{-7} g/ml), the contraction in response to transmural stimulation was abolished and replaced by a biphasic response. Bradykinin (5×10^{-8} g/ml), used as a reference drug for its direct action on the muscle, was unaffected. Tetrodotoxin (1×10^{-6} g/ml) added in the presence of atropine caused a further but not significant reduction of response to cerulein. The response to bradykinin was not affected by atropine and tetrodotoxin. In the presence of atropine plus tetrodotoxin, the response to cerulein was resumed at higher doses of polypeptide (1×10^{-6} g/ml). Hexamethonium (1×10^{-4} g/ml) reduced the response to cerulein by 25%, while bradykinin was not affected. The results indicate that the effects of cerulein on isolated human ileum are mediated mainly through cholinergic structures because atropine reduces its response. The stimulant effect of cerulein, however, appears to be at least partially independent of the cholinergic nervous system, because neither atropine nor tetrodotoxin completely abolished the contractions. The response to cerulein was only partially affected by hexamethonium, indicating that cerulein stimulates mainly at postganglionic sites. It is suggested that response remaining after atropine and tetrodotoxin is either directly on the smooth muscle cells or mediated through the release of a mediator at the level of the nerve endings.

3864 COMPARATIVE STUDIES ON THE EFFECTS OF BRADYKININ AND VAGAL STIMULATION ON MOTILITY

IN THE STOMACH AND COLON. *(E.)* Fasth, S.; Hulten, L.; Jahnberg, T.; Martinson, J. (Sahlgrenska Hosp., Univ. Goteburg, Sweden). *Acta Physiol. Scand.* 93(1): 77-84, 1975.

The effect of bradykinin on gastric and colonic motility was compared with the effects of vagal nerve stimulation in cats. Eighteen cats were anaesthesized and fitted with volume recording devices which allowed intragastric and intraluminal pressures to be kept constant. Intraaortic bradykinin (10 μg) caused a profound and prolonged gastric relaxation along with a marked and prolonged colonic contraction. The gastric relaxation closely mimicked the atropine resistant relaxation elicited by vagal stimulation. Bradykinin did not reproduce the vagal motility effects on colon smooth muscle but mimicked the atropine resistant expulsive contraction elicited by activiation of the pelvic nerves. The effects were not blocked by anti-adrenergic drugs. The results suggest that the gastric relaxation elicited by intraaortic bradykinin is not caused by an adrenergic mechanism or by a direct ganglion stimulating effect but is due to a direct effect on the gastric smooth muscles; further investigations are suggested to determine whether a kinin-like substance is involved.

3865 ELECTROMYOGRAPHY OF THE SPHINCTER OF ODDI: TECHNIC AND EXPERIMENTAL RESULTS IN THE RABBIT: EFFECT OF CERTAIN DRUGS.

(E.) Sarles, J. C.; Midejean, A.; Devaux, M. A. (Dig. Pathol. Res. Unit, INSERM, Marseille, France). *Am. J. Gastroenterol.* 63(3):221-231, 1975.

Electromyographic tracings of the rabbit sphincter of Oddi *in vivo* (50 rabbits) and *in vitro* (20 rabbits) were described, in addition to the effect of alcohol and various pharmacodynamic agents on the choledochoduodenal junction. Electromyographic activity was recorded by means of bipolar suction electrodes placed on the sphincter of Oddi and the adjacent duodenum. The bile duct was catheterized so that the pressure could be recorded. The sphincteric traces showed basal activity consisting of bursts of 1-8 spike potentials every 3-5 sec accompanied by a transient rise in biliary pressure. The patterns were different from those recorded for the duodenum in which the biliary pressure was not affected. The frequency and amplitude of the spike potentials increased with temperature and the rise in biliary perfusion pressure. Acetylcholine (1.8 mg/kg, i.v.), prostigmin (0.05 mg/kg, i.v.), and morphine hydrochloride (0.4 mg/kg, i.v.) increased the frequency and amplitude of the spike potentials and shortened the resting intervals. Inhaled amyl nitrite and i.v. hexamethonium (2 mg/kg/hr) reduced electrical activity. Atropine (0.2 mg/kg, i.v.) had a very slight depressant effect. Alcohol (1 g/kg) administered as an i.v. drip resulted in a substantial increase in the electrical activity of the sphincter and in biliary pressure. The effect was reduced by vagotomy and suppressed by hexamethonium (1 mg/kg/hr, i.v.) given 30 min before alcohol. The results suggest that the sphincter of Oddi is the site of basal contractile activity, consisting of rhythmic muscular contractions, which prevent the discharge of bile into the duodenum and temporarily raise the pressure in the lower end of the common bile duct.

3866 MOTILITY CHANGES IN THE ANTRUM AFTER PROXIMAL GASTRIC VAGOTOMY.

(E.) Kelly, M.; Kennedy, T. (R. Victoria Hosp., Belfast, Ireland). *Br. J. Surg.* 62(3):215-220, 1975.

The motility of the antrum in the normal animal was studied before and after truncal, selective and proximal gastric vagotomy. The resting and postprandial motor activity in the gastric antrum was observed in 6 dogs using a miniaturized mercury column strain gauge. There was a gradual increase in the amplitude of contraction during the first 2 hr after eating, which was maintained for 3 hr, and then declined For the first 45 min, terminal antral contraction occurred, partially retaining and triturating the gastric contents. After 45 min, the waves became sequential, symmetrical, increased in vigor, and actively pumped food into the duodenum. Truncal and selective vagotomy reduced the work capability to 20% of normal 1 month after operation; the waves were disorganized. Proximal gastric vagotomy abolished the braking mechanism and removed the initial inhibitory stimuli to antral motility. Within 1 month, the antrum regained 58% of its normal work capability and the contractions were well organized. The results indicate that the avoidance of a drainage operation in combination with proximal gastric vagotomy maintains an active and effective pyloric pump which recovers rapidly after operation.

3867 NEURAL ORGANIZATION OF ESOPHAGEAL PERISTALSIS: ROLE OF VAGUS NERVE.

(E.) Mukhopadhyay, A. K.; Weisbrodt, N. W. (Univ. Texas Med. Sch., Houston). *Gastroenterology* 68(3): 444-447, 1975.

A study was undertaken to determine the velocity of peristalsis in the smooth muscle area of the opossum esophagus before and after atropine administration and to evaluate the role of the vagus nerves in controlling the propagation of esophageal peristalsis. Tracheostomies were performed on animals of both sexes and the intraluminal pressures in the esophagus were measured with a pressure transducer recorder system. The velocity of peristalsis in the lower third of the esophagus was measured before and after atropine (100 μg/kg, i.p.) following the induction of swallowing by pharyngeal stimulation. In another group of animals, the vagus nerves were sectioned behind and between the carotid artery and jugular vein, and the esophageal contractions produced by electrical stimulation were measured after i.p. atropine (100 μg/kg) administration. The velocity of peristalsis in the lower third of the esophagus progressively decreased from 3.25 cm/sec to 1.83 cm/sec at the lower esophageal sphincter. After atropine administration, the velocity decreased from 3.1 cm/sec to 1.74 cm/sec at the lower esophageal sphincter; these changes were not significant. Electrical stimulation of the distal cut end of the vagus nerve induced peristaltic contractions, the velocities of peristalsis after electrical stimulation decreasing from 3.24 cm/sec to 1.84 cm/sec at the lower esophageal sphincter. The results indicate that the velocity of peristalsis in the smooth muscle area of the opossum esophagus has a caudally decreasing gradient. Bilateral cervical vagotomy and stimulation of the distal cut end initiated peristaltic contraction, indicating that the propagative nature of peristalsis in the smooth muscle area of the opossum esophagus has a caudally decreasing gradient. Bilateral cervical vagotomy and stimulation of the distal cut end initiated peristaltic contraction, indicating that the propagative nature of peristalsis in the smooth muscle segment of the body of the esophagus is controlled by a local mechanism within the esophagus rather than within the central nervous system.

3868. EFFECT OF VAGOTOMY ON ELECTRICAL ACTIVITY OF THE SMALL INTESTINE OF THE DOG. *(E.)*

Weisbrodt, N. W.; Copeland, E. M.; Moore, E. P.; Kearley, R. W.; Johnson, L. R. (Univ. Texas Med. Sch., Houston). *Am. J. Physiol.* 228(2):650-654, 1975.

The effect of bilateral thoracic vagotomy on the myoelectric activity of the small intestine was studied in conscious male mongrel dogs. The animals were implanted with electrodes spaced 25 cm apart along the serosal surface of the small intestine, and a cannula was placed in the most dependent portion of the stomach. Recordings were made with dogs in fasted and fed states. Two distinct patterns of myoelectric activity were recorded: one typical of the fasted state (the interdigestive myoelectric complex) and one typical of the fed state. After completion of the control recording periods, a truncal vagotomy was performed on each animal. Completeness of the vagotomy was confirmed by lack of a gastric secretory response to insulin. Gastric stasis occurred after vagotomy, so animal stomachs were emptied *via* the gastric cannula to obtain a fasted condition. Vagotomy had little or no effect on the fasted pattern of myoelectric activity, but the fed pattern was significantly altered in 2 animals. This alteration might have been due to the effect of vagotomy on gastrin release. It is concluded that nervous pathways within the vagus may exert some influence on the intestinal myoelectric activity, but that other neural-humoral pathways are probably also involved.

3869 EFFECT OF PROSTAGLANDINS E_1, E_2 AND $F_2\alpha$, AND PENTAGASTRIN ON THE GALLBLADDER PRESSURE IN DOGS. *(E.)*

Nakano, J.; McCloy, Jr. R. E.; Gin, A. C.; Nakano, S. K. (Univ. Oklahoma Coll. Med., Oklahoma City). *Eur. J. Pharmacol.* 30(1):107-112, 1975.

The effects of pentagastrin and prostaglandins E_1 (PGE_1), E_2, (PGE_2), and $F_2\alpha$ ($PGE_2\alpha$) on gallbladder pressure were studied in anesthetized dogs. The gallbladders of 34 dogs were exposed through an upper midline laparotomy. The various drugs were injected into a femoral vein and the effects on gallbladder and systemic arterial pressures monitored continuously. In some animals, the cystic duct was clamped. Both PGE_1 and PGE_2 (4 μg/kg) lowered gallbladder pressure when the initial pressure was higher than 5 mm Hg, but caused no significant change when the initial pressure was lower than 3 mm Hg; both significantly decreased the systemic arterial pressure. In contrast, $PGF_{2\alpha}$ (4 μg/kg) increased systemic arterial and gallbladder pressures regardless of the initial pressure. When the cystic duct was clamped, $PGF_{2\alpha}$ markedly increased gallbladder pressure, while both PGE_1 and PGE_2 increased it only slightly. Furthermore, $PGF_{2\alpha}$ appeared to constrict the sphincter of Oddi, while PGE_1 and PGE_2 relaxed it. Pentagastrin (200 μg/kg) initially decreased then slightly increased systemic arterial pressure and produced a significant monophasic decrease in gallbladder pressure regardless of the initial pressure. Pretreatment with indomethacin did not affect or slightly potentiated the cholecystokinetic effect of the prostaglandins, but abolished that of pentagastrin. The results suggest that gallbladder smooth muscle is markedly stimulated by $PGF_{2\alpha}$ and stimulated to a lesser degree by $PGE_1$and PGE_2. They also suggest that prostaglandins are possible mediators for the cholecystokinetic action of the gastrointestinal hormones.

3870 EFFECTS OF ACETYLCHOLINE RELEASING DRUGS ON ELECTRICAL ACTIVITIES OBTAINED FROM AUERBACH'S PLEXUS IN THE GUINEA PIG ILEUM. *(E.)*

Sato, T.; Takayanagi, I.; Takagi, K. (Fac. Pharm. Sci., Univ. Tokyo, Japan). *Jpn. J. Pharmacol.* 24(3): 447-451, 1974.

The effects of 5-hydroxytryptamine, sodium picrate, cerulein, and pentagastrin on the electical activities in Auerbach's plexus in the guinea pig ileum were studied. The ileal longitudinal muscle with Auerbach's plexus was removed from male animals and suspended in an organ bath filled with Locke-Ringer's solution. The drugs and various antagonists (atropine sulfate, hexamethonium bromide, nicotine bitartrate, and morphine hydrochloride) were injected into the bath and the responses of the tissue recorded using an isotonic lever. At 3×10^{-7} to 3×10^{-6} g/ml, 5-hydroxytryptamine increased the spike frequency in Auerbach's plexus; this was unaffected by pretreatment with atropine, hexamethonium, or nicotine. Sodium picrate (10^{-4} g/ml), cerulein (3×10^{-9} g/ml), and pentagastrin (5×10^{-7} g/ml) also increased the spike frequency, their effects similarly being little affected by atropine or hexamethonium. Tachyphylaxis was observed following repeated administration of pentagastrin at 10^{-6} g/ml, and large spikes were often simultaneously recorded with 5-hydroxytryptamine, cerulein, pentagastrin, and sodium picrate. The large spikes were inhibited by atropine and Mn^{++}, but not by tetrodotoxin. Morphine reduced the frequency of the single spikes elicited by 5-hydroxytrypamine as well as the 5-hydroxytryptamine-induced contraction of the isolated longitudinal muscle strip; morphine had a similar effect on the responses elicited by cerulein. The results suggest that the sites of action of these agonists are in Auerbach's plexus and that the agonists modify to a minimum extent the electrical activities of Auerbach's plexus *via* muscarinic and nicotinic receptors. Furthermore, these agonists probably accelerate the release of acetylcholine and contract the ileum.

3871 MECHANICAL RESPONSES TO CATECHOLAMINES IN ISOLATED STRIPS OF THE GUINEA-PIG STOMACH MUSCLE.

(E.) Yamaguchi, T.; Tomita, T. (Fac. Med., Kyushu Univ., Fukuoka, Japan). *Jpn. J. Pharmacol.* 24(6):911-922, 1974.

The effects of various catecholamines on the mechanical responses caused by electrical stimulation of excitatory and inhibitory nerves in the guinea pig stomach were studied. Strips of circular and longitudinal muscle from animals of both sexes were suspended in organ baths containing Krebs solution. Epinephrine hydrochloride, tetrodotoxin citrate, norepinephrine hydrochloride, isoproterenol hydrochloride, phentolamine mesylate, propranolol hydrochloride, and hyoscine butylbromide were injected into the organ baths, the blockers being applied 10-15 min prior to catecholamine application. The preparations were stimulated between two Ag-AgCl electrodes placed at opposite ends of the bath. In the circular muscles, the relaxation and biphasic response elicited by epinephrine and norepinephrine were partially suppressed by phentolamine and propranolol; the catecholamine-induced relaxation in the longitudinal muscles was inhibited by propranolol. α-Relaxation was more dominant in the circular muscles, while β-relaxation was more dominant in the longitudinal muscles. The contractions in both muscle types were mediated *via* α-effects, but the circular muscle was more sensitive to the α-effect while the longitudinal muscle was more sensitive to the β-effect. In the presence of propranolol, isoproterenol caused a monophasic contraction or a biphasic response in both circular and longitudinal muscle. The inhibition of the electrically evoked contractions by epinephrine and norepinephrine was abolished by phentolamine in both muscle types, but the electrically evoked relaxations were little affected. The data suggest that the suppressive action of the catecholamines is probably due to the prevention of acetylcholine release by activation of the α-receptors in the cholinergic nerves. The suppression of evoked contractions by isoproterenol was probably due to a direct action on the muscle rather than an effect on nervous elements.

3872 EFFECTS OF GASTROINTESTINAL HORMONES ON VASCULAR SMOOTH MUSCLE.

(E.) Fara, J. W. (Health Sci. Cent., State Univ. New York, Stony Brook). *Am. J. Dig. Dis.* 20(4):346-353, 1975.

The effects of secretin and cholecystokinin (CCK) on the mechanical activity of the rat portal vein were investigated and compared with those of isoproterenol, theophylline, and cyclic and dibutyryl cyclic AMP (cAMP). Thirty-three portal veins from male and female rats were mounted in Krebs-solution baths containing the various drugs being tested; some of the solutions contained 4-5 times the normal potassium ion concentration. Boots secretin (0.03-0.60 U/ml), pure natural secretin (0.18-0.60 U/ml), and CCK (0.12-0.60 U/ml) elicited dose-dependent decreases in the amplitude and simultaneous increases in the frequency of the spontaneous venous contractions. These effects were mimicked by isoproterenol theophylline, and cAMP. All agents tested were also effective in reducing potassium- or norepinephrine-induced tension. In addition, subthreshold doses of CCK and secretin elicited responses when given in combination, and the effects of the hormones at all dose levels were potentiated by theophylline. The mechanical responses to secretin, CCK, and isoproterenol were unaffected by atropine and phenoxybenzamine, and only the response to isoproterenol was blocked by propranolol. The data indicate that secretin and CCK have a direct inhibitory effect on rat portal vein activity and that this effect is not mediated through α- or β-adrenergic or cholinergic receptors. They also suggest that CCK, secretin, and isoproterenol exert their action on the portal vein through a cAMP mechanism. At least a part of the mechanism of hormone-induced mesenteric vasodilatation may involve a direct relaxing effect of the hormones on the vascular smooth muscle.

3873 A RAPID PULL-THROUGH TECHNIQUE FOR MEASURING LOWER ESOPHAGEAL SPHINCTER PRESSURE.

(E.) Dodds, W. J.; Miller, W. N.; Lydon, S. B.; Arndorfer, R. C. (Med. Coll. Wisconsin, Milwaukee). *Gastroenterology* 68(3):437-443, 1975.

Measurement of lower esophageal sphincter pressure by rapid pull-through technique was compared with that by conventional station pull-through technique. Twenty-four studies were performed on 12 normal volunteers using a 5-lumen catheter assembly. Sphincte pressure was measured by the conventional method, in which the catheter radial recording tips were withdrawn through the sphincter in 0.5 cm increments wit a 10-sec pause at each station, and the rapid method, in which the sensors were withdrawn manually at 0.5 -1.0 cm/sec during a 10-15 sec interval of suspended respiration. Two complete sets of studies were done 2-4 wk apart. First-study results from each subject were scored independently by different observers on 2 separate occasions, while those of the second study were scored once only by each observer. Intraobserver and interobserver scoring errors were calculated, and a variance analysis was done. In the 1st study, differences in intraobserver error were small, but were significantly less in the rapid technique (0.3) than the standard (1.3). Interobserver scoring error was greater for results from the standard technique than the rapid. Scoring errors were not sufficient to obscure pressure differences between subjects. Variance between intrasubject pull-throughs was significantly greater for standard (10.0-6.6 mm Hg) than for rapid (7.3-4.3 mm Hg) techniques. Data from the first and second studies showed pressures calculated from the rapid method to be slightly greater than those from the standard method (24.3 and 21.1 mm Hg, resp)--a significant difference. Calculation from either method correlated significantly between studies. It is concluded that intraobserver and interobserver scoring errors are less for recorded and calculated pressure obtained by the rapid method; the sphincter-gastric pressure gradient is slightly greater when calculated from the rapid method; and calculated pressure is reproducible for both methods.

3874 PLASMA CATECHOLAMINES AND POSTOPERATIVE GASTRIC EMPTYING AND SMALL INTESTINAL PROPULSION IN THE RAT.

(E.) Dubois, A.; Henry, D. P.; Kopin, I. J. (Natl. Cancer Inst., Bethesda, Md.). *Gastroenterology* 68(3):466-469, 1975.

The role of the adrenal medullary discharge of catecholamines in the inhibition of gastric emptying and small intestinal propulsion after laparotomy was examined using male Sprague-Dawley rats. Fasted demedullated and sham-demedullated rats were anesthetized and the small intestine and colon exteriorized, wrapped in gauze, and replaced after 30 min. Twelve hr later, 2 ml of a ^{51}Cr-labeled liquid test meal were administered *via* gastric tube and the rates of gastric emptying and propulsion of the meal into the distal small intestine were determined. The concentration of plasma catecholamines was determined by an enzymatic assay. Fourteen days after adrenal demedullation, the plasma catecholamine levels were significantly lower than in the sham-demedullated animals. Twelve hr after exteriorization of the small intestine, there was a significant increase in the plasma catecholamine levels of the sham-demedullated rats but not the demedullated rats. Gastric emptying before and after exteriorization of the intestine occurred at the same rate in the demedullated and sham-operated rats. Similarly, the 2 groups did not differ in the rate of small intestinal propulsion after a test meal; in both groups, the rate of transfer of the intestinal contents to the distal portion of the intestine was significantly retarded 12 hr after intestinal exteriorization. The results indicate that *in vivo*, circulating catecholamines have only a minor influence on gastric emptying and intestinal propulsion of a test meal.

3875 MODIFICATION OF 5-HT ACTION BY MAGNESIUM IONS ON THE GUINEA PIG ILEUM.

(E.) Singh, G. (Lady Hardinge Med. Coll., New Delhi, India). *Jpn. J. Pharacol.* 24(4):639-640, 1974.

The effects of different perfusion media on the responses of the guinea pig ileum to 5-hydroxytryptamine (5-HT) were studied. Ileal segments from mongrel guinea pigs were perfused with Tyrode's solution or mammalian Ringer's solution. Of 10 pieces of intestine from different animals, seven showed tachyphylaxis to 5-hydroxytryptamine when perfused with Tyrode's solution; the height of the contractions were increased substantially by placing the segments in the Ringer's medium. Subsequently, the action of graded doses of 5-hydroxytryptamine was studied in ileal segments perfused with Ringer's solution to which $MgCl_2$ had been added. $MgCl_2$ (1-2 x 10^{-4} g/ml) reduced or completely blocked the response to all doses of 5-hydroxytryptamine; it also reduced the response of the ileal segments to histamine. 5-Hydroxytryptamine failed to contract segments of depolarized guinea pig ileum perfused with K_2SO_4-Ringer's solution to which $CaCl_2$ had been added. The results suggest that 5-hydroxytryptamine may make calcium available for the contractile machinery of the guinea pig ileum by a process of depolarization. Antagonism between 5-hydroxytryptamine and magnesium may be secondary to an antagonism between calcium and magnesium.

3876 LOCAL SPECIALIZATION AT ILEOCECAL JUNCTION OF THE CAT AND OPOSSUM.

(E.) Conklin, J. L.; Christensen, J. (Univ. Hosp., Univ. Iowa, Iowa City). *Am. J. Physiol.* 228(4):1075-1081, 1975.

Characteristics which distinguish the ileocecal junction of the opossum from that of the cat were studied in 10 mature animals of each species. Serial 2-mm-wide transverse strips of muscularis propria were prepared from samples of ileum and colon taken from the region 1.5 cm above and about 1.5 cm below the ileocecal mucosal junction. These strips were separately stretched to determine the relation between length and tension and were separately subjected to electrical field stimulation. Anatomically, there was a thickening of the circular muscle layer in the ileal wall above the ileocolic mucosal junction in the cats but not in the opossums. In most cases the ileal strips of both species relaxed during electrical field stimulation, with tension returning to basal levels at the ends of the trains. This fall in basal tension during the stimulus train was seldom seen in the colonic strips of either species. All reponses to electrical field stimulation were abolished by tetrodotoxin (3 x 10^{-7} M) in the opossum and in the cat (3 x 10^{-6} M). In both species, the length-tension slopes were greatest just above the ileocecal junction where stimulus relaxation occurred. Tetrodotoxin (3 x 10^{-7} M) raised the basal tension in the ileal strips in both species and in the colonic strips only in the cat. The data indicate that the ileocecal junction muscle resembles that of the esophagogastric and gastroduodenal junctions in its relatively high degree of resistance to stretch and prominent neurogenic stimulus relaxation. However, in contrast to these other junctions, the ileocecal junction also possesses a tonic inhibitory innervation. The ileocecal junction appears to be characterized by a control system which differs from the systems of the ileum above and the colon below the junction.

3877 EFFECTS OF GASTROINTESTINAL HORMONES ON GASTROINTESTINAL MOTILITY AND ABSORPTION.

SECRETION AND METABOLISM

Stomach

3920 EFFECTS OF PREDNISONE ON GASTRIC SECRETION AND DEVELOPMENT OF STOMACH LESIONS IN SWINE. *(E.)* Zamora, C. S.; Kowalczyk, T.; Hoekstra, W. G.; Grummer, R. H.; Will, J. A. (Dep. Vet. Sci., Univ. Wisconsin, Madison). *Am. J. Vet. Res.* 36(1): 33-39, 1975.

The effects of prednisone on ulceration and gastric secretion was studied in crossbred weanling pigs. The pigs were treated for 19 days with i.m. saline or i.m. prednisone (10, 20, 40, 80, or 160 mg/day); all animals were also treated i.m. with a long-acting antibiotic preparation. In the second experiment, the gastric contents were collected from five pigs with simple gastric fistulas both before and during treatment with prednisone (10 mg/kg, i.m.). In the first experiment, the prednisone-treated pigs developed pathologic changes in the glandular region of the stomach, primarily in the fundic area and occasionally in the pyloric and cardiac mucosas. The characteristic lesion was hemorrhagic gastritis, which was associated with massive gastric hemorrhages in the animals given the larger doses of prednisone. Epithelial changes were observed in the esophageal area, but there were no ulcers. In the animals with gastric fistulas, administration of prednisone for 8 days produced a significant increase in the volume and acidity of the gastric secretion. In addition, the hexosamine output, but not its concentration, increased significantly during the treatment period. Prednisone did not produce an immediate change in gastric secretion; there was a latent period of 1-2 days before marked changes were observed. Peak changes were seen around the third or fourth day, after which the acidity of the gastric secretion gradually decreased to pretreatment levels. The results indicate that although increased acidity may be involved in the development of lesions in the glandular region of the stomach, other factors probably also have a role in the pathogenesis of steroid-induced stomach lesions in swine.

3921 THE INFLUENCE OF FOOD CONSUMPTION AND RUNNING ACTIVITY ON THE ACTIVITY-STRESS ULCER IN THE RAT. *(E.)* Pare, W. P. (VA Hosp., Perry Point, Md.). *Am. J. Dig. Dis.* 20(3):262-273, 1975.

The extent to which food consumption and running activity contribute to the development of the activity-stress ulcer was studied in male ARS/Sprague-Dawley rats. In the first experiment, rats housed in activity cages were exposed to a daily 1-hr feeding schedule; control animals in standard cages were food yoked to the activity rats. A similar procedure was followed in the second experiment, in which both activity and control groups contained naturally active and less active animals, and in the third experiment, in which the rats' normal light-dark cycle was reversed. In the fourth experiment, rats representing three different age groups, and presumably three activity levels, were exposed to the activity-stress situation. In the first experiment, the rats housed in the activity cages died within 21 days and developed extensive ulcers in the glandular stomach; the food-yoked controls did not die and remained ulcer-free. Rats demonstrating high running activity levels under *ad libitum* feeding conditions subsequently developed a higher incidence of ulcers than low-activity rats when exposed to the activity-stress situation. Attempts to attenuate activity and lesion incidence by reversing the light-dark schedule failed, but a higher mortality level in rats under the reversed light-dark condition was related to higher activity levels in these animals. In the fourth experiment, young rats with a high activity levels died sooner and developed more ulcers than older rats with low activity levels. These results suggest that running activity, and not reduced food intake, was critically involved in the development of the activity-stress ulcers in these experiments.

3922 THE EFFECTS OF BURIMAMIDE AND METIAMIDE ON GASTRIC SECRETION IN THE CONSCIOUS CAT.

(E.) Harris, D.; Smy, J. R.; Reed, J. D.; Venables, C. W. (Sch. Pharm., Sunderland Polytech., England). *Agents Actions* 4(5):311-313, 1974.

The effects of burimamide and metiamide on gastric acid secretion were studied in 10 cats with cannulated gastric fistulas. In four experiments, burimamide (2 mg/kg, i.v.), metiamide (4 mg/kg, i.m.), burimamide plus metiamide, and pentagastrin (6 μg/kg) were injected into the conscious animals; the gastric acid output was measured every 15 min. Burimamide significantly increased acid secretion over basal levels, the maximal increase occurring within 30 min of injection. Metiamide, on the other hand, had no significant effect on acid secretion. Although acid output was increased following the administration of burimamide plus metiamide, the response was significantly lower than that to burimamide alone. The total acid output in response to burimamide was only 18.5% of that observed in response to pentagastrin. These results suggest that burimamide has a partial agonistic action which is not shared by metiamide.

3923 BA^{++} ON THE RESTING FROG STOMACH: EFFECTS ON ELECTRICAL AND SECRETORY PARAMETERS.

(E.) Rangachari, P. K. (Univ. California Sch. Med., San Francisco). *Am. J. Physiol.* 228(2):511-517, 1975.

The effects of Ba^{++} on the electrical and secretory activities of the resting frog stomach were studied. Gastric mucosae from bullfrogs were bathed in nutrient solutions containing potassium penicillin, streptomycin sulfate, KCl, histamine acetylcholine, NaSCN, and/or $BaCl_2$ (0.1-2.0 mM). Low chloride solutions were prepared using glucuronic acid titrated with NaOH to neutral pH. Ba^{++} added to the nutrient solution increased resistance, decreased the potential difference, and stimulated acid secretion in comparison to stomachs bathed in normal solutions. Under short-circuit conditions, the increase in the acid secretory rate was accompanied by a decrease in short-circuit current. These changes were reversed by NaSCN (10 mM), suggesting that Ba^{++} had not impaired the current-generating mechanism *per se*. Histamine-induced acid secretion was associated with an increase in net Cl$^-$ flux, particularly the forward flux (N→S). Ba^{++} increased acid secretion with no increase in the forward flux, but with a decrease in the net Cl$^-$ flux. Histamine, in the presence of Ba^{++} and low-Cl$^-$ solutions, increased acid secretion and transmucosal resistance, suggesting the operation of a neutral pump in the secretion of HCl. The results suggest that Ba^{++} affects the movement of Cl$^-$ across the tissue and induces a competition for Cl$^-$ between the acid-secreting and current-generating mechanisms at the luminal surface.

3924 EFFECT OF ANTRECTOMY AND SUBSEQUENT VAGOTOMY ON THE SERUM GASTRIN RESPONSE TO FOOD IN DOGS.

(E.) Booth, R. A. D.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Ann. Surg.* 181(2):191-195, 1975.

The food-stimulated release of extra-antral gastrin was studied in mongrel dogs with denervated fundic Heidenhain pouches. Serum gastrin concentrations and acid secretion from the Heidenhain pouches were measured after an 18-hr fast and every 15 min for 3 hr following the ingestion of a 200 g meat meal. The dogs were then subjected to antrectomy, with gastrointestinal continuity restored by means of a Billroth I gastroduodenal anastomosis or a Billroth II gastro-jejunostomy. The effect of food on serum gastrin and gastric acid secretion was again measured 3 weeks later. A few days later, some of the dogs were subjected to bilateral truncal vagotomy; the food studies were repeated 3 weeks afterward. Serum gastrin was measured by radioimmunoassay. In all dogs, antrectomy significantly depressed the mean basal levels of serum gastrin and abolished the rise in serum gastrin shown by intact animals in response to a meat meal. Food-induced pouch acid secretion was also significantly lowered by antrectomy. Vagotomy after antrectomy increased the basal levels of serum gastrin, but did not restore the serum gastrin response to a meal. The results suggest that biologically active forms of gastrin are released from the antrum in response to food, while biologically inactive basal levels of gastrin apparently originate from extra-antral sources. The post-vagotomy increase in basal (static) gastrin suggests vagal control of the metabolism of static, extra-antral gastrin.

3925 ELECTROPHYSIOLOGIC RESPONSES OF THE CANINE GASTRIC MUCOSA TO ENDOTOXIN, EPINEPHRINE, AND HEMORRHAGE.

(E.) Chou, A. C.; Jacobson, E. D.; Shanbour, L. L. (Univ. Texas Med. Sch., Houston). *Circ. Shock.* 2(1):13-20, 1975.

The early electrophysiologic responses of an epithelial membrane were measured during endotoxin and hemorrhagic shock using an *in vivo* canine stomach preparation. A segment of the oxyntic gland area of the stomach was exposed in fasted mongrel dogs of both sexes. The potential difference across the stomach was monitored with a pair of calomel electrodes. In some animals, the LD_{100} dose of endotoxin (6 mg/kg) was given as a rapid i.v. bolus (group II) or by intra-arterial infusion (group III). In group IV, oligemic shock was induced by removal of blood from the femoral artery, and group V was given epinephrine (1 μg/kg/min) directly into the gastric artery for 10 min. In a second experiment, the effects of phentolamine (2.3 mg/kg given as 2 boluses and by continuous infusion) on the potential difference after endotoxin was studied. In the third experiment, the effect of endotoxin and aminopyrine (given at 20 mg/kg loading dose and subsequent infusion at a rate of 5 mg/kg/hr) clearance from the gastric mucosal flap was measured. Given as a bolus, endotoxin caused an immediate decrease in the potential difference and an increase in the equivalent electrical resistance across the stomach; the same dose of endotoxin given as a continuous infusion produced no such changes. Oligemic shock and epinephrine had similar effects to those produced by the endotoxin bolus. The decrease in potential difference and increase in equivalent electrical resistance produced by endotoxin were blocked by phentolamine, and endotoxin produced an increase in the gastric mucosal blood flow as determined by aminopyrine clearance. The results suggest that the effect of endotoxin on the electrophysiology of the gastric mucosa is mediated primarily through the release of epinephrine, which acts directly on the active transport processes rather than through the induction of gastric mucosal ischemia.

3926 INTERACTION OF SECRETIN AND CARBAMINOYLCHOLINE ON GASTRIC SECRETION IN CATS. *(E.)*

Vagne, M.; Perret, G. (INSERM, Edouard-Herriot Hosp., Lyon, France). *Digestion* 11(3/4):215-225, 1974.

Acid, pepsin, and gastric mucus secretion were studied during stimulation with a cholinergic, secretin, and a combination of both in three cats equipped with a gastric fistula and a Heidenhain pouch. Gastric secretion from both the gastric fistula and Heidenhain pouch was collected for three 1-hr periods following experiments using carbaminoylcholine (10 μg/kg for first hr, 20 μg/kg for second hr), synthetic secretin (0.5 U/kg for first hr, 3 U/kg for second hr), and a combination of these. Carbaminoylcholine slightly stimulated acid secretion and strongly stimulated pepsin and mucus secretion using determinations of uronic acid as representative of polysaccharides and fucose as representative of glycoproteins. Synthetic secretin induced a small stimulation of pepsin, uronic acid, and fucose secretions. Secretin added to cholinergic stimulation decreased the acid response and increased pepsin and mucus responses. The results suggest that, in cats, fundic mucus secretion is under both cholinergic and hormonal control.

3927 INHIBITION OF GASTRIC ACID SECRETION IN THE RAT BY ORALLY-ADMINISTERED SYNTHETIC PROSTAGLANDIN ANALOGUES: ENANTIOMORPHS OF 15-HYDROXY-15-METHYL-9-OXOPROSTANOIC ACID. *(E.)*

Lippman, W. (Biochem. Pharmacol. Dep., Ayerst Lab., Montreal, Canada). *J. Pharm. Pharmacol.* 26(10):831-833, 1974.

The effects of orally-administered enantiomorphs of 15-hydroxy-15-methyl-9-oxoprostanoic acid (AY-22469) on basal gastric acid secretion and on the incidence of diarrhea were studied in mice and rats. The synthetic prostaglandin racemate AY-22469 inhibited basal gastric secretion with an ED$_{50}$ of 4.3 mg/kg. The *ent*-isomer was similarly active with a parallel log dose-response curve, while the *nat*-isomer was 2.8-fold less effective than the *ent*-isomer with a parallel log dose-response curve. There was no effect on the volume of gastric juice produced. In mice, AY-22469 at a dose level up to 240 mg/kg caused diarrhea in 13% of the animals; at a similar dose level, the incidence of diarrhea was 25% with the *ent*- and *nat*-isomers. In rats, AY-22469 caused diarrhea with an ED$_{50}$ of 120 mg/kg. The antisecretory activity of AY-22469 and the enantiomorphs appears to be due to their action on the acid concentration; cyclic adenosine-3',5'-monophosphate may be involved in this action. AY-22469 and its enantiomorphs may be useful therapeutic agents for the treatment of gastric hypersecretion and peptic ulcers.

3928 ALTERATIONS IN SECRETORY PATTERNS FOLLOWING ANTRECTOMY IN RATS WITH PAVLOV POUCHES.

(E.) Lundell, L. (Inst. Physiol., Univ. Lund, Sweden
J. Physiol. (Lond.) 245(3):737-754, 1975.

The gastric secretory response to various stimuli was studied in conscious female Sprague-Dawley rats provided with Pavlov pouches. The antrum was also removed in some rats, gastrointestinal continuity being reestablished by an end-to-end gastroduodenostomy. The maximal acid secretory capacity was 60% lower in the antrectomized than in the intact Pavlov pouch rats 3 weeks after surgery; the difference increased with time as the maximal capacity of the intact animals increased. Antrectomy also reduced the interdigestive secretion of acid. Acid secretion in response to i.v. pentagastrin infusion (maximal dose 8 μg/hr for 6 hr) was reduced by about 50% 3 weeks after antrectomy and by about 65% after 6 weeks. The antrectomized and intact rats did not differ in this respect, however, when the responses were related to the maximal secretory capacity. The dose-response curve to paentagastrin revealed a reduced responsiveness to submaximal doses of this agent, following antrectomy. The maximal acid secretory response to i.v. histamine (15.625-2000 μg/hr) was also reduced after antrectomy, although the sensitivity to submaximal infusions of histamine appeared to be increased. The mean secretory output in response to 2-deoxy-D-glucose (50 mg/kg, i.v.) was reduced by about 65%, and that to food (2-3 gm standard pellet diet) was reduced by about 85% following antrectomy. After antrectomy, a background infusion of pentagastrin enhanced the secretory response to 2-deoxy-D-glucose and food, but did not restore the responses to the levels seen in the intact rats. The feeding responses as related to the maximal secretory capacity were, however, similar in both groups when pentagastrin was infused into the antrectomized animals. The interdigestive secretion of pepsin was reduced by about 60% after antrectomy, while the peak response to 2-deoxy-D-glucose was about twice the interdigestive level in both groups. The food-stimulated increase in pepsin secretion was of longer duration in the antrectomized rats. The results suggest that the reduction in maximal acid secretory capacity after antrectomy is due primarily to a parietal cell hypoplasia, and that the functional performance of the parietal cells is altered after antrectomy to a degree that the response to methacholine plus histamine is not a true gauge of the maximal secretory capacity.

3929 DECREASED INCIDENCE OF INDOMETHACIN-INDUCED GASTRIC ULCERATION IN RATS BY BILE DUCT DIVERSION. *(E.)* Abtahi, F. S.; Djahanguiri, B. (Fac. Med., Univ. Tehran, Iran). *Br. J. Surg.* 62(2): 113-114, 1975.

The effect of bile drainage into different sites in the small bowel on the incidence of indomethacin-induced gastric ulceration was studied in male and female Sprague-Dawley rats. The fasted animals were left unoperated, sham-operated, or fitted with a cannula inserted into the bile duct; the other end of the cannula was inserted into the small bowel 0, 2.5, 5, 7.5, or 10 cm distal to the ampulla of Vater. The animals were then infused i.p. with saline or indomethacin (40 mg/kg) in saline solution. The stomachs were examined for signs of ulceration 4 hr later. Indomethacin produced ulceration in 100% of the unoperated and sham-operated animals. In the operated rats in which the cannula had been inserted 0, 2.5, 7.5, and 10 cm from the ampulla of Vater, indomethacin produced 100, 80, 50, 30, and 10% ulceration, resp. The incidence of indomethacin-induced ulceration was significantly reduced in the latter three groups of operated rats compared with the unoperated, sham-operated, and operated rats in whom the cannula was inserted 0 cm from the ampulla of Vater. The results show that the exclusion of bile reflux from the stomach prevents the appearance of indomethacin-induced gastric ulceration in fasted rats. They suggest that bile reflux plays an as yet undetermined role in the pathogenesis of indomethacin-induced gastric ulceration in rats.

3930 LIPOATE EFFECT ON CARBOHYDRATE AND LIPID METABOLISM AND GASTRIC H$^+$ SECRETION. *(E.)* Harris, J. B.; Alonso, D.; Park, O. H.; Cornfield, D.; Chacin, J. (San Francisco Gen. Hosp., Calif.). *Am. J. Physiol.* 228(3):964-971, 1975.

Some of the factors regulating the use of carbohydrates and lipids as energy sources by frog gastric mucosa were examined. Acid secretion and oxygen consumption were measured in the gastric mucosa of *Rana catesbeiana* following treatment with pyruvate, thiamine, thiamine pyrophosphate, lipoate, glucose, lactate, histamine, and/or various fatty acids. Both acid secretion and oxygen consumption by the mucosae were sharply stimulated by lipoate; this was followed by a rapid decline to below control values. Glucose or lactate alone had no effect on either parameter, and pyruvate alone caused only a slight stimulation of oxygen consumption. However, treatment of lipoate-treated mucosae with any of these compounds increased the stimulatory effect of the lipoate and markedly slowed the rate of decline subsequent to maximum stimulation. Various fatty acids had a moderate-to-large stimulatory effect on both acid secretion and oxygen consumption. However, lipoate pretreatment decreased the stimulatory effect of butyrate by 56%, that of decanoate by 87%, and that of palmitate by 60%; propionate became an inhibitor in the presence of lipoate. Lipoate also increased oxidation of exogenously supplied fatty acids compared to the levels seen in the absence of exogenous substrate. Lipoate-treated mucosae did not respond to histamine, but the addition of glucose restored responsiveness. The results indicate that the β-oxidation of fatty acids plays a major role in the acid secretory process and that it is centrally involved in the previously reported stimulation of acid secretion by cyclic AMP and histamine.

3931 CHEMICAL STIMULATORY MECHANISM IN GASTRIC SECRETION. *(E.)* Cieszkowski, M.; Konturek, S. J.; Obtulowicz, W.; Tasler, J. (Med. Acad., Krakow, Poland). *J. Physiol. (Lond.)* 246(1):143-157, 1975.

The effects of bovine serum albumin, pepsin-digested albumin, an amino acid mixture, liver extract, and mannitol (control) on the serum gastrin level, gastric mucosal blood flow, and acid secretion from the Heidenhain pouch were measured in three mongrel dogs. Distention of the Heidenhain pouch with mannitol or albumin (particularly pepsin-digested albumin) at pH 5.0 produced similar pressure-related increases in acid secretion, reaching a peak of only 10% of the maximal response to histamine. The highest acid output (about 80% of the maximal response to histamine) was obtained with liver extract; an amino acid mixture containing all essential amino acids stimulated acid secretion to a lesser degree. In no case did the secretions from gastric or pancreatic fistulas or the serum gastrin level change from basal values. I.v. atropine (100 μg/kg/hr) and irrigation of the pouch with 50 ml of 0.1% atropine or 2% xylocaine solution significantly depressed the pouch response to liver extract; irrigation with 0.5% acetylcholine did not affect the response, and i.v. urecholine (10 μg/kg/hr) increased the response. The pouch response to chemical stimulation by peptic digests was greatly potentiated by combining this with distention of the oxyntic gland area. When the pH of the liver extract in the Heidenhain pouch was gradually decreased from 5.0 to 1.0, there was a concomitant decrease in acid secretion and in the mucosal blood flow, both falling to the basal level at pH 1.0. Exogenous secretin given in graded doses from 0.5-8.0 U/kg/hr caused a small, dose-related inhibition of the acid response to liver extract and an increase in the mucosal blood flow; there was no significant change in the serum gastrin level. The results suggest that the products of protein digestion, polypeptides and free amino acids, are potent chemical stimulants of acid secretion from the oxyntic gland area. The stimulation of this area by peptic digests induces acid secretion by a local, gastrin-independent, partially neural reflex mechanism which is sensitive to pH, pressure, and secretin.

3932 CIRCADIAN PLASMA GASTRIN PATTERNS IN FEEDING AND FASTING MAN. *(E.)* Moore, J. G.;

Wolfe, M. (Univ. Utah Coll. Med., Salt Lake City). *Digestion* 11(3/4):226-231, 1974.

The effects of feeding and fasting on the circadian pattern of plasma gastrin concentrations were studied in human volunteers. Basal gastric acid collections were obtained every 24-hr from healthy male adults. The hourly secretory pattern, which described a circadian rhythm, was compared to serial plasma gastrin levels in subjects who underwent 24-hr gastric intubation and aspiration, subjects who ate and exercised freely, and subjects who fasted but were unintubated. A circadian rhythm of plasma gastrin levels was observed only in subjects who ate and exercised freely. The results confirm previous findings that the circadian pattern of gastric acid secretion is unrelated to plasma gastrin levels and support the belief that the circadian rhythm of plasma gastrin levels is a result of the effects of feeding on antral gastrin release.

3933 PENTAGASTRIN INCREASES PHENYLALANINE AND DECREASES HISTADINE INCORPORATION INTO PROTEINS OF RAT STOMACH. *(E.)* Evans, D. C.; Lin, T. M. (Res. Lab., Eli Lilly Co., Indianapolis, Indiana). *Res. Commun. Chem. Pathol. Pharmacol.* 10(3):597-600, 1975.

The action of pentagastrin on the incorporation of [^{14}C] L-phenylalanine and [^{14}C] L-histidine into the stomach and duodenum proteins of rats was studied. Sixty female rats were treated with [^{14}C] L-phenylalanine or [^{14}C] L-histidine (20 μCi/kg, i.p.) 1 hr before receiving pentagastrin (250 μg/kg, s.c.). One hr after injection of pentagastrin the incorporation of [^{14}C] L-phenylalanine into the proteins of the squamous and fundic portions of the stomach was significantly increased by 18% and 17.5%, resp. The uptake of [^{14}C] L-histidine into the proteins was significantly decreased in the squamous region (-24%), fundic region (-18%), and duodenal region (-16%). Incorporation of histidine and phenylalanine into the proteins of the pylorus was not significantly affected. The results support the view that gastrin plays a dual role on gastric function: a trophic action to enhance protein synthesis; and a stimulating action on histidine metabolism favoring histamine production.

3934 DOES HISTAMINE HAVE TWO VASODILATOR ACTIONS ON THE GASTRIC MUCOSA? *(E.)* Reed, J. D.; Sanders, D. J. (Med. Sch., Univ. Newcastle upon Tyne, Engalnd). *Agents Actions* 5(1):1-3, 1975.

Oxygen consumption and extraction were measured during gastric stimulation with histamine and gastrin pentapeptide to determine whether there is an extra mucosal blood flow component in addition to that linked to parietal cell activity. Gastric activity was stimulated by histamine (45 μg/kg, i.v.) in three cats and by pentapeptide (2 μg/min) in five. Samples of gastric venous blood were taken at the rate of 1 ml/min; hemoglobin concentration and % oxygen saturation were measured. Steady state conditions were ensured by taking values obtained between 30 and 60 min from start of stimulation. During gastrin pentapeptide stimulation, there was significantly less mucosal blood flow/U H$^+$ compared to the histamine responses. Oxygen consumption was dependent upon acid secretion in a similar way for both histamine and gastrin stimulation. The degree of oxygen extraction from the gastric circulation was significantly less during histamine stimulation than during gastrin stimulation. The results support the hypothesis that histamine causes a vasodilatation in the gastric mucosa in two ways, a direct dilator action and one associated with secretory activity.

3935 PEPSIN OUTPUT AFTER DISRUPTION OF THE HUMAN GASTRIC MUCOSAL BARRIER BY TAUROCHOLI ACID. *(E.)* Ivey, K. J.; Parsons, C. (R. Prince Alfred Hosp., Sydney, Australia). *Am. J. Dig. Dis.* 20(4):362-364, 1975.

Pepsin output in man was studied after the gastric mucosal barrier was altered by taurocholic acid. Test solutions containing 10 mM taurocholic acid in 160 mM HCl were instilled into the stomachs of five healthy volunteers. Significant back diffusio of H$^+$ and exsorption of Na$^+$ occurred, but there was no significant increase in pepsin output compared to control studies using HCl alone. The results show that 160 mM HCl increases pepsin output in man but altering the gastric mucosal barrier with taurocholic acid in 160 mM HCl does not produce any greater output of pepsin.

3936 EVIDENCE FOR OXYNTOPYLORIC REFLEX FOR RELEASE OF ANTRAL GASTRIN. *(E.)* Debas, H. T.; Walsh, J. H.; Grossman, M. I. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Gastroenterolog* 68(4):687-690, 1975.

The effect of distention of the vagally innervated oxyntic gland area on the release of gastrin from the vagally innervated pyloric gland area was studied in dogs. Three dogs were prepared with vagally innervated pouches of both the oxyntic gland area and the pyloric gland area (antrum). When the antral pouch was filled but not distended with 0.1 M NaHCO$_3$, graded distention of the oxyntic pouch caused graded increases in serum gastrin and graded increases in acid secretion from the oxyntic pouch. When the antral pouch was filled with 0.1 M HCl, graded distention of the oxyntic pouch evoked no increase in serum gastrin and the acid responses from the oxyntic pouch were much smaller than when the antrum was alkaline. The results support the hypothesis that distention of the oxyntic gland area initiates an oxyntopyloric reflex that causes release of gastrin from the pyloric gland area.

3937 EFFECTS OF INTRADUODENAL AMINO ACIDS, FATTY ACIDS, AND SUGARS ON SECRETIN CONCENTRATIONS. *(E.)* Boden, G.; Essa, N.; Owen, O. E. (Temple Univ. Health Sci. Cent., Phila., Pa.). *Gastroenterology* 68(4):722-727, 1975.

The effects of amino acids, fatty acids, and iso- and hypertonic solutions of sugars on serum concentrations of immunoreactive secretin (IRS) were studied in 21 anesthetized dogs. The test substances, an 8.5% amino acid mixture, a 50 mM Na oleate solution, an oleic acid bile mixture, 5% fructose, 40% sucrose, and 9% NaCl solutions were infused intraduodenally at constant rates. HCl (160 mM) was infused at the end of most experiments to demonstrate responsiveness of the animals. Infusion of amino acids, Na oleate, the oleic acid bile mixture, and 5% fructose all failed to significantly change portal or femoral venous IRS concentrations. NaCl (9%) caused a slight depression; 40% sucrose caused a slight increase in IRS concentrations; however, neither change was statistically significant. HCl significantly increased portal and femoral venous IRS concentration and was the only substance that increased pancreatic flow and bicarbonate excretion. The results suggest that oleic acid, amino acids, fructose, and hypermolar solutions at the concentrations tested have no major effect on IRS release; HCl is the only physiological substance shown to reproducibly promote secretin secretion.

3938 THE EFFECT OF CARBENOXOLONE ON CHANGES IN CANINE AND HUMAN GASTRIC MUCOSA CAUSED BY TAUROCHOLATE AND ETHANOL. *(E.)* Gordon, M. J.; O'Brien, P.; Skillman, J. J.; Silen, W. (Harvard Med. Sch., Boston, Mass.). *Surgery* 77(5):707-714, 1975.

The effect of carbenoxolone on gastric mucosal permeability was studied in canine gastric pouches and in healthy human subjects; its effect on ethanol- and taurocholate-induced changes was also determined. Three dogs were prepared with an antrectomy and a vagally denervated gastric pouch. Perfusion of the canine pouches with sodium taurocholate (40 mM) was associated with an increase in H+ back diffusion. The effect was not diminished by 10 days of carbenoxolone treatment. A significant increase of gastric mucosal permeability was observed in six normal human subjects after instillation of ethanol (20% v/v). After 3 weeks of oral ingestion of carbenoxolone, there was inconsistent protection against ethanol-induced increases in gastric mucosal permeability. Basal secretion of H^+ and post-ethanol H^+ secretion appeared to be diminished by carbenoxolone. The results suggest that carbenoxolone does not protect against taurocholate- and ethanol-induced increases in gastric mucosal permeability in the dog or in man and that its beneficial effect on gastric ulcer is by a mechanism other than prevention of H^+ back diffusion.

3939 THE ROLE OF BILE REFLUX IN THE DEVELOPMENT OF COLD-RESTRAINT GASTRIC LESIONS. *(E.)* Meeroff, J. C.; Paulsen, G.; Guth, P. H. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Am. J. Dig. Dis.* 20(4):365-369, 1975.

The role of bile reflux in the development of gastric mucosal lesions during cold-restraint stress was studied in the rat. Sprague-Dawley rats (40) were randomized into four groups: one underwent sham operations with no cold-restraint stress; the other three were subjected to cold-restraint stress for 3 hr following sham operations, pyloric ligation, or bile duct ligation. The stomachs were then removed and the severity of lesions recorded; hematocrit readings were made on blood from the hearts. The mean lesion scores of all groups exposed to cold-restraint stress were similar but much higher than those of the unrestrained sham-operated group. Mean hematocrit readings in all groups exposed to cold-restraint stress were lower than in the control group. There was a moderate correlation between severity of mucosal lesions and hematocrit reading. The results suggest that bile reflux is not necessary for formation of cold-restraint stress lesions in the rat and that hematocrit readings may be useful in measuring blood loss secondary to experimental mucosal lesions.

3940 SIGNIFICANCE OF LOCAL CIRCULATORY DISTURBANCE IN THE EXPERIMENTAL PRODUCTION OF GASTRIC ULCER. *(E.)* Sekine, T.; Shiratori, T. (Tohoku Univ. Sch. Med., Sendai, Japan). *Tohoku J. Exp. Med.* 114(2):121-130, 1974.

The relation between experimental production of gastric ulcer and local circulatory disturbance was investigated in dogs by ligating gastric vessels accompanied with or without histamine injection. Dogs (62) were divided into five groups and the following observations made in each group: macroscopic findings of the gastric mucosa; microscopic findings of ulcer; incidence of production of ulcers; and acid secretory response to histamine. Gastric ulcers were similar to those seen in humans except for little regeneration of mucosa or proliferation of connective tissue at the base and margin of the ulcer. The incidence of gastric ulcers was extremely high in groups having had both histamine administration (50 mg histamine dihydrochloride in beeswax, i.m.) and gastric vessel ligation compared with groups having had only histamine. Gastric acid secretion in response to histamine also showed a fall in free acidity and a marked decrease in volume after ligation of gastric vessels. The results suggest that decrease in mucosal resistance induced by ligation of gastric vessels, rather than gastric acid secretion, may play an important role as an etiologic factor in the production of gastric ulcers.

3941 EFFECT OF HYPNOTIC SUGGESTION OF RELAXATION ON BASAL AND BETAZOLE-STIMULATED GASTRIC ACID SECRETION. *(E.)* Stacher, G.; Berner, P.; Naske, R.; Schuster, P.; Bauer, P.; Starker, H.; Schulze, D. (Psychiatric 1st Surg. Clin., Univ. Vienna, Austria). *Gastroenterology* 68(4):656-661, 1975.

The effect of relaxation suggestion in hypnosis on basal and betazole stimulated gastric acid secretion was examined in four healthy female volunteers (21-24 yr-old) susceptible to hypnosis. Acid output was measured by intragastric titration and a pH-sensitive telemetry capsule. Three series of experiments, each lasting 3 hr, were carried out: (1) after 1 basal hr, administration of 1.7 mg/kg betazole s.c.; 2) after the basal hr, administration of saline s.c. and induction of hypnosis; relaxation was suggested for 1 hr, after which posthypnotic amnesia was suggested and the subject awakened; and 3) procedure as in experiment 2 but 1.7 mg/kg betazole s.c. instead of saline. Each subject underwent two of each series. A completely crossed 4-factorial analysis of variance, accounting for treatment, time, replication, and subject factors was performed. Suggestion of relaxation in hypnosis resulted in a significant reduction of unstimulated (2.16 mEq/15 min) as well as betazole-stimulated (0.62 mEq/15 min) acid secretion and in a decrease of gastric motility. Both effects were reversed after the termination of hypnosis. It is suggested that these effects originate in the central nervous system and are mediated *via* an alteration of the stimulating and/or inhibiting tone of the autonomic nervous system.

3942 GASTRINS IN HUMAN ANTRUM, DUODENUM AND PERIPHERAL CIRCULATION.

(E.) Vinik, A. I.; Grant, B. J.; Novis, B. (Dep. Med., Univ. Cape Town, South Africa). *S. Afr. Med. J.* 49(8):255-257, 1975.

The nature of the gastrins extracted from human antrum, duodenum, and peripheral circulation was studied using blood samples and biopsy specimens from 3 patients. The major form of gastrin found in the pyloric antrum was the heptadecapeptide form; the duodenum contained primarily high-molecular weight gastrin (MW 3,900) and almost no heptadecapeptide gastrin. Fasting serum samples contained mostly high-molecular weight gastrin. The results, in conjunction with previous observations that arginine-stimulated gastrin is comprised of mostly the heptadecapeptide and the lower molecular weight forms, suggest that stimulated gastrin is derived mainly from the pyloric antrum and that the large molecular series are produced by G cells; specific local cleavage processes then determine the nature of gastrin released.

3943 THE INFLUENCE OF HYPERCALCEMIA ON GASTRIC SECRETION AND SERUM GASTRIN CONCENTRATION IN INTACT AND THYRO-PARATHYROIDECTOMIZED RATS.

(E.) Johansson, H.; Krause, U.; Nilsson, F.; Lundqvist, G. (Univ. Hosp., Uppsala, Sweden). *Ups. J. Med. Sci.* 79(3):161-163, 1974.

Gastric acidity and serum gastrin concentration were measured in thyro-parathyroidectomized (14) and sham-operated (14) rats after calcium infusion. Calcium was given in a dose of 2.6 mg/100 g in 0.5 ml administered by continuous infusion at 0.1 ml/min. Plasma gastrin and calcium concentrations were determined 15, 30, 60, 90, and 120 min after the start of the calcium infusion. Gastric juice was collected between 0-2 and 2-4 hr. A moderate H^+ decrease, and unchanged Cl^- concentration and plasma gastrin level were demonstrated in both experimental groups. Although calcium may increase the release of gastrin in man, the results of these experiments showing no change in the serum gastrin concentration after calcium infusion led to the conclusion that such a mechanism does not exist in the rat.

3944 DIRECT INHIBITION OF GASTRIC ACID AND PEPSIN SECRETION BY GROWTH-HORMONE RELEASE-INHIBITING HORMONE IN CATS.

(E.) Gomez-Pan, A.; Reed, J. D.; Albinus, M.; Shaw, B.; Hall, R.; Besser, G. M.; Coy, D. H.; Kastin, A. J.; Schally, A. V. (Dep. Med., Univ. Newcastle upon Tyne, England). *Lancet* 1(7912):888-890, 1975.

The inhibitory action of growth-hormone release-inhibiting hormone on acid and pepsin secretion stimulated by pentagastrin was studied in six conscious cats prepared with gastric fistulas at least 1 yr earlier and compared with the inhibition of food-stimulated acid secretion. On separate days each animal was infused for 60 min with growth-hormone release-inhibiting hormone (10 μg/kg/min) starting 15 min before the s.c. injection of pentagastrin (6 μg/kg) or the ingestion of food, and continuing for 45 min. Gastric juice was collected throughout the period and for 75 min. Growth-hormone release-inhibiting hormone inhibited gastric acid and pepsin secretion in response to pentagastrin and food stimulation in cats. This effect was mediated by a direct action on the parietal and peptic cells. No evidence of a post-inhibitory acid or pepsin secretory rebound was obtained. A compound of hypothalamic origin, then, can exert a direct effect on exocrine secretion. It is suggested, in view of its widespread actions and its presence in relatively high concentrations in various organs apart from the hypothalamus, that growth-hormone release-inhibiting hormone, in addition to its action as a hypothalamic regulatory hormone, might also be responsible for local coordination of endocrine and exocrine secretion.

3945 DIRECT INHIBITION OF GASTRIC ACID BY GROWT HORMONE RELEASE-INHIBITING HORMONE IN DOGS

(E.) Barros D'Sa, A. A. J.; Bloom, S. R.; Baron, J. H. (R. Postgrad. Med. Sch., London, England). *Lancet* 1(7912):886-887, 1975.

To determine if growth-hormone release-inhibiting hormone has any direct action on gastric acid production independent of its effect on gastrin release cyclic growth-hormone release-inhibiting hormone was infused at a rate of 20 μg/kg/hr into four dogs with gastric fistulas. Gastric acid output fell sharply in response to three stimuli of acid production: a meal; and pentagastrin (0.1 μg/kg/hr) and histamine (0.5 μg/kg/hr) infusions. During a 2-hr infusion of growth-hormone release-inhibiting hormone after a meat meal, gastric acid was totally inhibited in each dog with some return of secretion after stopping the infusion. Pentagastrin-stimulated acid production was inhibited 97% by growth-hormone release-inhibiting hormone infusion and histamine-stimulated acid secretion was inhibited 71%. Recovery of acid secretion to almost pre-growth-hormone release-inhibiting hormone levels was seen by the end of the 3rd hr. The fact that acid output was inhibited during pentagastrin administration suggests that growth-hormone release-inhibiting hormone has a direct effect on the gastric parietal cell.

3946 INTESTINAL PHASE OF GASTRIC ACID SECRETION: AUGMENTATION OF MAXIMAL RESPONSE OF HEIDENHAIN POUCH TO GASTRIN AND HISTAMINE. *(E.)* Debas, H. T.; Slaff, G. F.; Grossman, M. I. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Gastroenterology* 68(4):691-698, 1975.

A study was conducted to determine whether serum gastrin increases during the intestinal phase of gastric acid secretion, to investigate the interactions of the intestinal phase with histamine and with endogenous and exogenous gastrin, and to examine the effect of vagotomy on these interactions. In four antrectomized dogs with gastric fistulas and Heidenhain pouches, a liver extract solution of $NaHCO_3$ as control was infused into the gastric fistula for 6 hr. During the last 2 hr, a maximal dose of either pentagastrin (8 µg/kg/hr) or histamine (80 µg/kg/hr), or saline as control, was given i.v. The studies were repeated after truncal vagotomy. Liver extract alone caused a small Heidenhain pouch response but produced no rise in serum immunoreactive gastrin. Intestinal perfusion with liver extract augmented the maximal Heidenhain pouch response to pentagastrin three-fold before and two-fold after vagotomy. The maximal Heidenhain response to histamine was augmented 1 1/2 fold both before and after vagotomy. In another group of three dogs provided with antral pouches, gastric fistulas, and Heidenhain pouches, infusion of liver extract into the gastric fistula produced a similar augmentation of the Heidenhain pouch maximal response to endogenous gastrin released by antral distention with liver extract. It is concluded that liver extract releases entero-oxyntin from the intestine, a hormone capable of augmenting the maximal Heidenhain pouch responses to both gastrin and histamine, that this hormone is distinct from gastrin, that vagotomy does not abolish its release, and that its release by food in the intestine accounts for the greater maximal Heidenhain pouch response to a meal than to exogenous gastrin.

3947 MODEL FOR ISOLATED GASTRIC CELLS TO STUDY THE ENZYMATIC MECHANISM INVOLVED IN ACID SECRETION. *(Fr.)* Lewin, M.; Cheret, A. M.; Grelac, F.; Soumarmon, A.; Ghesquier, D.; Girodet, J. (Bichat Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 7(4):295-296, 1974.

SECRETION AND METABOLISM

Pancreas

3974 PURIFICATION AND PROPERTIES OF SUBUNITS OF STEROL ESTER HYDROLASE FROM RAT PANCREAS. *(E.)* Calame, K. B.; Gallo, L.; Cheriathundam, E.; Vahouny, G. V.; Treadwell, C. R. (George Washington Univ. Med. Cent., Washington, D.C.). *Arch. Biochem. Biophys.* 168(1):57-65, 1975.

A procedure for the purification of subunits of sterol ester hydrolase and the results of studies concerning the nature of the interaction of enzyme subunits with cholic acid and its taurine conjugate were described. Subunits of sterol ester hydrolase from rat pancreas were solubilized by treatment of tissue homogenate with 0.5% digitonin. The crude, solubilized enzyme subunit was shown to have a molecular weight of approximately 70,000 by Sephadex G-200 gel filtration. The subunit was purified 500-fold by a combination of ammonium sulfate fractionation, hydroxylapatite, and gel-filtration chromatography. The subunits had been shown to aggregate in the presence of cholic acid or sodium taurocholate to a 400,000 molecular-weight form, which is the active enzyme. Three types of differential inactivation studies (thermal, guanidine hydrochloride, and pH) indicated significantly greater stability of the active enzyme when compared to the subunits. The data support the tentative conclusion that a conformational change or series of changes accompanies the binding of the bile salt to the enzyme subunits, which results in their aggregation and enzyme activity.

3975 IN VITRO STUDIES ON INTERACTION OF RAT PANCREATIC LIPASE AND COLIPASE WITH BILIARY LIPIDS.

(E.) Lairon, D.; Nalbone, G.; Domingo, N.; Lafont, H.; Hauton, J.; Julien, R.; Rathelot, J.; Canioni, P.; Sarda, L. (Res. Group. Lipid Transp., INSERM, Marseilles, France). *Lipids* 10(4):262-265, 1975.

The interaction of lipase with biliary lipids was studied in the presence and absence of colipase. Rat pancreatic juice and bile were collected separately by cannulation, and rat pancreas was homogenized and centrifuged. The supernatant and the collected pancreatic juice were gel filtered, and the lipase and colipase fractions separated out. Rat bile (1.0 ml containing 3 mg/ml phospholipid) was mixed with either 0.1 ml of the lipase fraction (300 enzyme U), 1.2 ml of the colipase fraction (445 cofactor U); or 0.1 ml lipase and 1.0 ml colipase. The mixtures were stirred for 2 hr and filtered through a gel column. Lipase activity was determined at pH 9.0 and bile phospholipids were extracted with chloroform-methanol, and the phosphorus content estimated. When lipase was mixed with bile, the major part of the enzyme was eluted at 2.3 void volumes, and very little activity was associated with the phospholipids that emerged at 2.0 void volumes. A large portion of colipase was associated with these phospholipids, however. When both lipase and colipase were mixed with bile, the major enzyme activity was associated with the phospholipids in a high molecular weight complex including colipase. It is concluded that colipase is present in the complex formed by lipase with biliary or pancreatic lipids, that colipase is essential for the formation of the high molecular weight form of the enzyme, and for the attachment and function of lipase at interfaces.

3976 STUDIES ON DISPERSED PANCREATIC EXOCRINE CELLS. II. FUNCTIONAL CHARACTERISTICS OF SEPARATED CELLS.

(E.) Amsterdam, A.; Jamieson, J. D. (Rockefeller Univ., New York, N.Y.). *Cell Biol.* 63(3):1057-1073, 1974.

Functional characteristics of guinea pig pancreatic exocrine cells isolated by a procedure described in a previous paper by the same authors were assessed by studying the ability of the cells to synthesize, transport, and concentrate exportable proteins into zymogen granules and to release the sorted products in response to secretogogues. The ability of isolated cells to incorporate labeled amino acids ([^{14}C] leucine) into secretory proteins was assessed biochemically and by quantitative electron microscope autoradiography. Incorporation remained linear for up to 4 hr incubation at levels equivalent to those of pancreatic slices and ranged from 1,700-2,000 nM leucine/mg DNA. Over 95% of the exocrine cells in the population were viable, and all appeared to be equally active in incorporating amino acids. The capacity of separated cells to transport, concentrate, and store exportable proteins was monitored by electron microscope autoradiography on populations pulse labeled with [^{3}H]leucine and chase incubated for periods up to 4 hr. The same overall pathway previously mapped in pancreatic slices was followed by secretory proteins in separated cells, although in quantitative studies a defect was noted in the rate of conversion of condensing vacuoles to zymogen granules. Secretogogue responsiveness was assessed by monitoring discharge of labeled secretory proteins or of amylase in response to carbamylcholine and cerulein. While the separated cells released secretory proteins linearly for up to 4 hr in response to both secretogogues, the net release was about 50% less than that previously noted for pancreatic slices and required a 10 times higher concentration of stimulant. The defect may represent alteration in receptors due to the protease used for dissociation. It is concluded that separated exocrine cells retain their ability to process secretory proteins stepwise and vectorially which is consistent with preservation of structural polarity and that these cells should prove useful and satisfactory for a number of studies not requiring prolonged incubation times. The system, however, exhibits a number of defects including those related to inefficient concentration of proteins in condensing vacuoles, suboptimal response to secretogogues, and a slow decay with time as evidenced by loss of DNA from the system.

3977 THE EFFECT OF ELECTRICAL VAGAL STIMULATION ON CANINE PANCREATIC EXOCRINE FUNCTION.

(E.) Kaminski, D. L.; Ruwart, M. J.; Willman, V. L. (Dep. Surg., St. Louis Univ., Mo.). *Surgery* 77(4): 545-552, 1975.

The effect of electrical vagal stimulation on the canine pancreatic exocrine function was studied in conscious dogs by stimulating intact thoracic vagus nerves, the distal ends of cut vagus nerves in animals with intact gastric denervation, and the distal ends of cut vagus nerves in dogs whose stomachs had previously been selectively denervated. The dogs were fasted for 18 hr prior to each experiment, and during the experiments they received i.v. NaCl solution; gastric and pancreatic secretions were collected and measured every 15 min. Electrical stimulation of intact vagus nerves produced no significant change in the pancreatic output, the bicarbonate output, output of the secretin-stimulated pancreas, or protein output. Stimulation of both intact nerves did produce a significant increase in protein concentration and an emetic response associated with increased mucus and acid production by the stomach, which dissipated during the stimulation period. Stimulation of the distal ends (efferent fibers) of the cut vagus nerves in dogs with intact gastric innervation significantly increased the volume and protein output of the pancreas and the acid output of the stomach. Stimulation of the distal ends of cut right and both vagus nerves in animals whose stomachs had been selectively denervated significantly increased the volume and protein output of the pancreas without increasing the output of acid by the stomach. The data indicate that the canine pancreas is innervated directly by vagal fibers, which when stimulated produce an increase in the protein (enzyme) output and the volume of secretion. Maintenance of the pancreatic response following denervation of the stomach suggests that the response is primarily the result of direct vagal innervation and is not produced by gastrin released from the antrum.

3978 EFFECT OF HYPOBARIC HYPOXIA ON PANCREATIC SECRETION STIMULATED BY FOOD AND BY INTRADUODENAL INFUSION OF HYDROCHLORIC ACID. *(Pol.)*

Mroczka, J.; Sieppel-Maciejewska, K.; Bilski, R.; Konturek, S. (Acad. Med., Krakow, Poland). *Przegl. Lek.* 31(10):847-851, 1974.

Seven dogs with pancreatic fistulas were put into a baric chamber and pancreatic secretion stimulated in the first series of experiments by a mean meal (25 g/kg) and in the second series by intraduodenal infusion of 0.1 N hydrochloric acid (8 mEq/hr). The barometric pressure was decreased to approximately 1/2 atmosphere for 2 hr, and pancreatic juice was collected every 15 minutes. The volume and bicarbonate and protein outputs were determined and compared to controls. After the meat meal the volume of the pancreatic juice secreted during the first hr decreased 50% and during the second hr, 62% (22 and 13 ml, resp., as compared to 45 and 35 ml, resp. in controls). Bicarbonate output decreased 66% after 1 and 76% after 2 hr (1.95 and 1.05 mEq/hr, resp., as compared to 5.66 and 4.35 mEq/hr, resp. in controls). Protein contents decreased 30% after 2 hr (1315 mg and 895 mg resp. in the experimental group and 1343 mg and 1180 mg in controls). After the pressure returned to normal, the values of the measured parameters in the experimental group exceeded those in controls. When HCl was instilled into the duodenum the decreases were less pronounced than in the first series. The volume decreased 23%, bicarbonates 33%, and protein 33%. Lower values persisted in this series, even after pressure was increased to normal values. It is concluded that hypoxia connected with lowering of atmospheric pressure causes a marked inhibition of pancreatic secretion.

3979 ACTION OF SOME SYMPATHOMIMETIC AMINES UPON THE EXTERNAL SECRETION OF THE PANCREAS IN THE RAT. *(Fr.)*

Roze, C.; Debray, C.; de La Tour, J.; Souchard, M.; Vaille, C. (Bichat Hosp., Paris, France). *J. Pharmacol. (Paris)* 5(2):155-172, 1974.

Male CF Wistar rats under urethane anesthesia with acute pancreatic fistula were studied for the effects of various substances on pancreatic secretion. Epinephrine and norepinephrine increased the output of pancreatic juice by a factor of 2.5 after 10 min of i.v. perfusion at concentrations of 0.13 μM/kg/min and 0.232 μM/kg/min, resp. Isoproterenol had the same effect, but it was more marked and occurred at lower concentrations. At a concentration of 0.05 μM/kg/min, pancreatic secretion rose to about 75% of the maximal secretory capacity induced by secretin. The logarithmic relation of dose/effect approximated a linear function. Propranolol (2 mg/kg i.v.) produced a moderate and prolonged decrease in the basal pancreatic output, and delayed and decreased the effect of isoproterenol administered after the propranolol. Phenoxybenzamine alone (2 mg/kg) had a marked and very prolonged stimulating effect on pancreatic output. Association of phenoxybenzamine and propranolol did not block the effect of isoproterenol more than did propranolol alone. Sparteine, which inhibits the hyperglycemia produced by the urethane anesthesia, was administered with isoproterenol to determine whether the urethane affected the apparent effect of isoproterenol. It was found that the effect of isoproterenol remained the same. The pancreatic output of bicarbonates is increased by isoproterenol stimulation. Total proteins and amylase output is either unchanged or slightly increased by the sympathomimetic amines, doubtless due to a washing out effect. Propranolol has a prolonged decreasing effect, and phenoxybenzamine has a prolonged increasing effect on the pancreatic output of proteins and amylase, which reflects variations in water output rather than in concentration of protein and amylase. The results suggest an α-adrenergic inhibitor and β-stimulant effect, which diverges from the classical picture of uniquely inhibitor sympathetic effects demonstrated in the dog, cat, and guinea pig. This evidence also diverges from the picture of stimulation of receptors associated with an increase in intracellular AMP_c concentration demonstrated *in vitro* for the rat, rabbit, cat, and mouse. It may be that in the anesthetized rat, AMP_c plays a role in hydrolytic secretion.

3980 METHADONE INHIBITION OF CENTRAL VAGAL PANCREATIC STIMULATION INDUCED BY 2-DEOXY-D-GLUCOSE. DESENSITIZATION BY REPEATED ADMINISTRATION. *(Fr.)*

Vaille, C.; Roze, C.; de La Tour, J.; Souchard, M.; Debray, C. (Bichat Hosp., Paris, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 279(20):1641-1644, 1974.

A study was undertaken in Wistar CF rats to determine whether chronic administration of methadone had any effect on methadone-induced suppression of pancreatic stimulation produced by 2-deoxy-D-glucose (2DG). Rats were given methadone hydrochloride (5 mg/kg/day s.c., gradually increased to 7.5, 10, 12.5, and 15 mg/kg/day) over a 2 or 4 week period. After methadone treatment, rats were anesthetized with urethane and double biliary and pancreatic fistulas were established. After measurement of basal pancreatic secretion, 5 mg/kg methadone hydrochloride was injected s.c., followed, 5 min later, by 75 mg/kg i.v. of 2DG. Pancreatic secretion in these rats was compared with that in rats given 2DG alone or methadone plus 2DG without methadone pretreatment. In rats not pretreated with methadone, injection of methadone followed by 2DG had no effect on the output of pancreatic juice or protein. In rats given methadone for 2 weeks, acute methadone injection suppressed and delayed the stimulation produced by 2DG. After 4 weeks of methadone pretreatment, acute methadone injection no longer blocked pancreatic stimulation induced by 2DG but increased it. Parallel changes occurred in total protein and amylase secretion. In rats pretreated with methadone, basal pancreatic secretion (both volume and total protein) was significantly increased after surgery, but returned to control values within a few hours. This increased basal secretion may be due either to catecholamine release induced by urethane anesthesia or by hyperfunction of vagal secretory neurons.

3981 EFFECT OF EXTRAGASTRIC AND TRUNCAL VAGOTOMY ON PANCREATIC SECRETION IN THE DOG. *(E.)* Debas, H. T.; Konturek, S. J.; Grossman, M. I. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Am. J. Physiol.* 228(4):1172-1177, 1975.

The effect of extragastric vagotomy on pancreatic secretion was examined in four mongrel dogs with chronic pancreatic and gastric fistulas and compared to the effect of subsequent transthoracic truncal vagotomy in the same animals. Dose-response studies of pancreatic bicarbonate and protein secretion were done with i.v. infusions of secretin, octapeptide of cholecystokinin, and 2-deoxyglucose. The pancreatic response to a meal of beef liver (15 g/kg) and intraduodenal perfusion of graded concentrations of HCl, sodium oleate, and tryptophan were also studied. Each stimulant was studied on two occasions in each of three stages: control; after extragastric vagotomy; and after transthoracic truncal vagotomy. During each test, the gastric fistula was kept open. Pancreatic juice was collected continuously and separated into 15-min samples. The responses to secretin, octapeptide of cholecystokinin, and to duodenal HCl perfusion were either unaltered or only slightly decreased by either extragastric or truncal vagotomy. Basal pancreatic secretion and the responses to duodenal perfusion of oleate and tryptophan were markedly depressed by extragastric vagotomy. Extragastric vagotomy also reduced pancreatic responses to a meal and to 2-deoxyglucose. Subsequent truncal vagotomy caused still further reduction, possible by depressing antral gastrin release. These findings indicate that tonic vagal activity contributes to basal pancreatic secretion but has little effect on the response of the pancreas to secretin or cholecystokinin, or on the release of secretin from the intestine. It is suggested that the decreased pancreatic response to intestinally perfused oleate and tryptophan seen after extragastric vagotomy could be caused either by interruption of reflex paths between gut and pancreas or by interference with cholecystokinin. It is concluded that any advantage that selective vagotomy may have over truncal vagotomy in the treatment of duodenal ulcer probably cannot be attributed solely to an effect on the pancreas.

SECRETION AND METABOLISM

Hepatobiliary Tract

3994 EFFECT OF PHENOBARBITAL, SPIRONOLACTONE AND PREGNENOLONE-16α-CARBONITRILE ON BILE FORMATION IN THE RAT. *(E.)* Von Bergmann, K.; Schwarz, H. P.; Paumgartner, G. (Inst. Clin. Pharmacol., Univ. Bern, Switzerland). *Naunyn. Schmiedeberg's Arch. Pharmacol.* 287(1):33-45, 1975.

The effects of phenobarbital, spironolactone, and pregnenolone-16 α-carbonitrile on bile flow and bile lipid secretion were studied in adult male Sprague-Dawley rats. Phenobarbital sodium (8 mg/100 g, once daily), spironolactone (10 mg/100 g, twice daily), pregnenolone-16α-carbonitrile (3.5 mg/100 g, twice daily), saline, or gum arabic in water were administered by stomach tube for 4 days. Twenty-four hr after the last infusion, the bile duct was cannulated and the bile collected over three 10-min periods. In a second study, rats pretreated as above were infused with sodium taurocholate and the effect on the bile determined as above. Phenobarbital, spironolactone, and pregnenolone-16α-carbonitrile increased bile flow but did not alter bile salt excretion. During bile salt infusion, phenobarbital decreased the secretion of cholesterol and phospholipid to 39% and 49% of control values, resp.; however, spironolactone and pregnenolone-16α-carbonitrile more than doubled cholesterol excretion without influencing the output of phospholipid. As a result, phenobarbitol decreased the degree of cholesterol saturation while spironolactone and pregnenolone-16α-carbonitrile increased it. The findings indicate that different types of enzyme inducers may differ in their effects on biliary lipid secretion. Thus, depending on its influence on the cholesterol saturation of the bile, an inducer could contribute to or prevent the formation of cholesterol gallstones.

3995 HORMONAL CONTROL OF THE POTASSIUM LEVEL IN ISOLATED RAT LIVER CELLS. *(E.)* Barnabei, O.; Leghissa, G.; Tomasi, V. (Lab. Comp. Physiol., Univ. Bologna, Italy). *Biochim. Biophys. Acta* 362 (2):316-325, 1975.

Liver cells isolated from nonfasted female Wistar rats were incubated in media containing epinephrine, theophylline, insulin, ouabain, and/or glucagon, and the effects on potassium uptake and on the cyclic AMP levels of the cells were monitored. Liver cells isolated by the method of Berry and Friend (1969) contained about 48 μEq K+/g. Although 44% of the potassium was lost when the cells were kept at 4 C for 5 hr, the initial ion levels were restored by incubation at 37 C. Ouabin, epinephrine, and epinephrine plus theophylline inhibited the uptake of potassium by these cells; insulin partially counteracted the inhibiting effect of epinephrine, but had no effect on the basal potassium levels. Liver cells isolated by the procedure of Seglen (1972) were able to synthesize glycogen from glycose and contained a much higher level of potassium (102.2 μEq/g). Again, epinephrine and theophylline inhibited the uptake of K+, as did monobutyryl cyclic AMP and ouabain. Epinephrine and theophylline, alone and in combination, also increased the cellular levels of cyclic AMP; both epinephrine and glucagon produced, respectively, a 2- and 4-fold increase in cyclic AMP after only 2 min of incubation at 37 C. Ouabain and insulin had no effects on the cyclic AMP levels. The results suggest that the epinephrine-stimulated efflux of K+ in isolated liver cells may be due to an inhibition of the activity transport of potassium; this effect is probably mediated by cyclic AMP.

3996 EFFECT OF DIPHENYLHYDANTOIN ON THE HEPATIC MICROSOMAL ETHANOL OXIDIZING SYSTEM IN THE RAT. *(E.)* Andreasen, P. B.; Bremmelgaard, A. (Rigshosp., Copenhagen, Denmark). *Pharmacology* 12(4-5): 237-243, 1974.

The effect of diphenylhydantoin (DPH) on the hepatic microsomal ethanol-oxidizing system was investigated in female Wistar rats. The animals received 5-10 or 33-37 daily i.p. injections of DPH (75 mg/kg) or isotonic saline, after which the liver was removed and the microsomal protein and cytochrome P-450 content and lactate dehydrogenase and ethanol-oxidizing activities were determined. In the rats treated with DPH for 5-10 days, the microsomal lactate dehydrogenase activity was significantly elevated over control values; all other parameters were within normal limits. In the rats treated for 33-37 days, the liver weight, lactate dehydrogenase activity, cytochrome

P-450 content, and microsomal ethanol-oxidizing activity were all significantly elevated over control values. The hepatic cytochrome P-450 content and microsomal ethanol-oxidizing activity were significantly correlated, as were the hepatic lactate dehydrogenase activity and the microsomal ethanol-oxidizing activity. The results suggest that the interaction between ethanol and DPH metabolism may be mediated *in vivo* at the microsomal level.

3997 OXIDATION OF ETHANOL BY HEPATIC MICROSOMES OF ACATALASEMIC MICE. *(E.)* Lieber, C. S.; DeCarli, L. M. (Bronx VA Hosp., N.Y.). *Biochem. Biophys. Res. Commun.* 60(4):1187-1192, 1974.

Acetaldehyde production was used to assess ethanol oxidation by the liver microsomes of acatalasemic mice. The hepatic microsomes of Cs^b acatalasemic and Cs^a control mice were incubated *in vitro* with ethanol (50 mM) and a NADPH-generating system, and the activity of the microsomal ethanol-oxidizing system (MEOS) was measured. When subjected to heat inactivation, the liver microsomes of the actalasemic mice displayed decreased catalytic activity, but the NADPH-dependent MEOS remained unaffected. Even without heat inactivation, the NADPH-dependent metabolism of ethanol was much more active than the H_2O_2-mediated system, while the microsomes of the control mice showed equal rates of H_2O_2- and NADPH-dependent ethanol oxidation. The addition of catalase to the Cs^b liver microsomes *in vitro* markedly increased the capacity of the microsomes to oxidize ethanol in the presence of an H_2O_2-generating system and abolished this difference between the 2 strains of mice. In the presence of the catalase inhibitor azide, control Cs^a microsomes behaved similarly to the microsomes of the Cs^b animals. The selective persistence in the Cs^b mice of NADPH-dependent ethanol oxidation contrasting with the reduction in the H_2O_2-mediated metabolism of ethanol supports the existence of a catalase-independent ethanol-oxidizing system.

3998 PLASMA AND HEPATIC BINDING OF INDOCYANINE GREEN IN GUINEA PIGS OF DIFFERENT AGES. *(E.)* Hwang, S. W. (Natl. Inst. Environ. Health Sci., Research Triangle Park, N.C.). *Am. J. Physiol.* 228 (3):718-724, 1975.

The binding of indocyanine green (ICG) to the plasma and bile proteins of guinea pigs of varying ages was studied as was the uptake and efflux of ICG from liver slices. Protein binding was studied by a gel-filtration method in which plasma or bile samples from guinea pigs ranging in age from 1 day to adult were eluted with ICG in Sephadex columns. An ultracentrifugation method was used to study ICG binding to liver tissue, and the uptake of ICG by and efflux of ICG from liver slices was studied by placing fresh liver slices in beakers containing Krebs-Ringer-phosphate medium. The ICG in the plasma was almost totally bound to the plasma protein and there was no significant difference in binding between newborn and adult animals. The binding of ICG to biliary protein was also similar in all age groups. However, particulate fractions of liver from adult guinea pigs showed a higher ICG binding capacity than those from newborn animals at all ICG concentrations measured. The uptake of ICG by liver slices involved mostly active processes. The slice-to-medium (S/M) ratio of ICG was lowest in the liver preparations from the newborn animals, but the S/M ratio for adult animals was lower than that for 10-day-old animals. Liver slices from adult guinea pigs showed the fastest ICG efflux rates, the slowest rates being observed with the slices from the newborn animals. The results suggest that the degree of ICG binding to plasma and biliary proteins is not significantly different in newborn and adult guinea pigs. The incomplete development of ICG uptake and release mechanisms in the liver of the newborns may at least partially account for the lower biliary excretory capacity for ICG in the neonate.

3999 PHOSPHOLIPIDS AS CINCHOCAIN ACTION SITE DURING INHIBITION OF LIPOPEROXIDATIVE REACTIONS IN RAT LIVER MICROSOMES. *(E.)* Mishin, V.; Tsyrlov, I.; Gromova, O.; Lyakhovich, V. (State Inst. Med. Novosibirsk, USSR). *Hoppe Seyler's Z. Physiol. Chem.* 355(5):626-632, 1974.

The mechanism and site of action involved in the dibucaine hydrochloride-induced inhibition of microsomal lipid peroxidation was studied. Liver microsomes from male Wistar rats were incubated with dibucaine hydrochloride and NADPH- and ascorbate-dependent lipid peroxidation; the peroxidation activity of cytochrome P-450, the activity of NADPH-cytochrome reductase, and the binding of cinchocain with cytochrome P-450 were measured. Dibucaine hydrochloride inhibited oxygen consumption during NADPH- and ascorbate-dependent lipid peroxidation, but did not affect the cytochrome P-450 catalyzed decomposition of linoleic acid hydroperoxide. Dibucaine hydrochloride also did not hinder the process of microsomal electron transport from NADPH to cytochrome P-450. Metyrapone, a classical type II substrate, competitively interferred with the binding of dibucaine hydrochloride to cytochrome P-450, and phosphatidylethanolamine markedly weakened the inhibiting effect of dibucaine hydrochloride on microsomal lipid peroxidation. In addition, dibucaine hydrochloride considerably raised liver microsome hydrophobicity, increasing the quantum yield of 8-aniline-1-naphthalene sulfonate fluorescence in the lipid phase. The results suggest that an increased phospholipid hydrophobicity and a resultant decreased accessibility of the phospholipids for peroxidative reactions is responsible for the dibucaine hydrochloride-induced inhibition of microsomal lipid peroxidation.

4000 ACUTE CHOLESTASIS INDUCED BY LITHOCHOLIC ACID IN THE RAT. A FREEZE-FRACTURE REPLICA AND THIN SECTION STUDY. *(E.)* Miyai, K.; Mayr, W. W.; Richardson, A. L. (Sch. Med., Univ. California San Diego, La Jolla). *Lab. Invest.* 32(4):527-535, 1975.

Ultrastructural changes in lithocholic acid-induced cholestasis were studied by freeze-fraction techniques in female Wistar rats with bile fistulas. Sodium lithocholate was continuously infused i.v. (0.1 or 0.2 μM/min/100 g) for up to 4 hr. The higher dose induced complete cholestasis within 2-3 hr; the lower dose reduced the biliary output to less than 10% of the preinfusion level by the 3rd hr. Ultrastructural changes, primarily localized to the bile canaliculi and the pericanalicular region, were seen 30 min after the onset of bile acid infusion. Dilation of the bile canaliculi, loss of canalicular microvilli, prominence of the pericanalicular ectoplasm, and a characteristic lamellar transformation of the canalicular membrane developed, which become more prominent and widespread with time. The freeze-fracture replica study revealed that the canalicular microvilli became transformed through widening and flattening into multilamellar foldings. Intramembranous granules of the canalicular membrane appeared to have become redistrubuted, being few or absent in the transformed regions. In addition, a sharply angulated, crystalline material was seen in occasional bile canaliculi. This material appeared as a negative image in thin sections, indicating its solubility in organic solvents which were used for dehydration. With the lower dose of lithocholic acid, subcellular changes were similar to, but less severe and widespread than, those induced by the high dose. It is suggested that the hepatic ultrastructural changes which accompany lithocholic acid-induced acute cholestasis are attributable to the accumulation of this compound in the bile canaliculus and its vicinity. Lithocholic acid presumably causes an asymmetric perturbation in the molecular organization of the canalicular membrane which results in ultrastructural alterations and failure of fluid transport. In addition, precipitates of lithocholic acid appear to form in the bile canaliculi and may contribute to cholestasis.

4001 AN ETIOLOGIC BASIS FOR FATTY LIVER AFTER JEJUNOILEAL BYPASS. *(E.)* Hollenbeck, J. I.; O'Leary, J. P.; Maher, J. W.; Woodward, E. R. (Coll. Med., Univ. Florida, Gainesville). *J. Surg. Res.* 18(2):83-89, 1975.

An investigation undertaken in an attempt to prevent liver failure and fatty metamorphosis after jejunoileal bypass in experimental animals is described. An obesity bypass procedure was performed on eight healthy mongrel dogs. The intestine was divided 24 in from the pylorus and anastomosed end-to-side to the terminal ileum 12 in from the ileocecal valve. The blind end of the bypassed intestine was closed and a liver wedge biopsy performed. At subsequent monthly intervals the animals were operated upon, wedge biopsies were obtained, and aerobic and anaerobic cultures of bacterial flora were taken 12 in from the proximal end of the excluded limb. Four of the dogs received doxycycline hyclate, 100 mg/day p.o., while the other four received no antibiotics. All of the dogs survived the original procedure and experienced diarrhea as a sequelae of the operation; the diarrhea subsided within 10 days of the operation. Bacteriologic studies of the cultures taken from the defunctionalized intestine revealed *Bacteroides fragilis, Bacteroides species,* or both in all of the animals in the control group while none of the animals treated with doxycycline hyclate grew *Bacteroides*. It is suggested that *Bacteroides* organisms within the bypassed segment produce a hepatotoxic endotoxin. It was proposed that after obesity bypass, *Bacteroides*-specific antibiotics given p.o. may prevent post-bypass liver failure.

4002 BIOCHEMISTRY OF PEROXYSOME IN LIVER CELLS. *(Ger.)* Sies, H. (Inst. Physiol. Chem. Phys. Biochem., Univ. Munich, Germany). *Angew. Chem.* 86(22):789-824, 1974.

Biochemical studies on hepatocellular peroxysome are reviewed. The principal enzyme of peroxysome is catalase which is able to metabolize hydrogen peroxide both catalytically and peroxydatically. Catalase in peroxysome is associated with hydrogen peroxide-supplying oxidases. An active intermediate catalase-Fe^{3+}-H_2O_2 (complex I) is responsible for the peroxysomal H_2O_2 metabolism. Organ photometric investigations of intact, hemoglobin-free perfused rat liver for the selective measurement of Complex I is suitable for the dynamic study of the H_2O_2 metabolism taking place in the nanomol range. The frequency (quotient of rate of H_2O_2 formation and catalase heme concentration) can be increased to about 100/min by intracellular stimulation of the H_2O_2 production by glycolate and urate, against less than 10/min as measured in steady state. The predominantly peroxidatic oxidation of hydrogen donors, such as methanol and ethanol, at low frequencies at the expense of catalatic oxidation is of significance for normal and pathological metabolism. The catalatic oxidation of ethanol and methanol is stimulated by intensified H_2O_2 formation. Disturbances in hepatic metabolism in alcoholic states may be influenced by the administration of pyrazole derivatives with simultaneous stimulation of the peroxidatic metabolism of alcohol.

4003 ENZYME PROFILES OF MAMMALIAN BILE. *(E.)* Holdsworth, G.; Coleman, R. (Dep. Biochem., Univ. Birmingham, England). *Biochim. Biophys. Acta* 389(1):47-50, 1975.

The relations of the specific activities of bile enzymes to those in the hepatocytic plasma membrane was investigated. Bile was obtained from ox, sheep, pig, and rat, and liver homogenates were also prepared from these animals. Bile samples were also obtained from human patients. The following enzymes were assayed in both the bile samples and their corresponding liver homogenates: 5'-nucleotidase, alkaline phosphodiesterase I, L-leucyl-β-napthylamidase, Mg^{++}-ATPase, acid phosphatase, aryl sulfatase, succinate dehydrogenase, aryl esterase, LDH, and alcohol dehydrogenase. There were significant amounts of alkaline phosphodiesterase I, and smaller amounts of L-leucyl-β-naphthylamidase, 5'-nucleotidase and alkaline phosphatase (the four plasma membrane-bound enzymes) in the bile of each species. The intracellular enzymes (acid phosphatase, succinate dehydrogenase, LDH, and alcohol dehydrogenase) were completely absent from the bile. Polypeptide profiles of the bile samples as determined by electrophoresis showed a small number of bands when compared with those of the corresponding liver homogenates. It is concluded that preferential release of plasma membrane protein components is a consistent feature of bile salt secretion.

4004 INDUCTION OF HEPATIC ALKALINE PHOSPHATASE BY A SUBSTANCE IN BILE.

(E.) Jerksy, J. (Dep. Surg., Univ. Witwatersrand, South Africa). *S. Afr. J. Surg.* 12(4):255-257, 1974.

The effects of bile infusion on the production of serum alkaline phosphatase was studied in normal baboons. Bile was aspirated from the gallbladders of normal baboons and fractionated into 5 fractions, and 50 ml of each fraction was infused into 4 additional baboons. Infusion of whole bile was followed by a sharp rise in the serum alkaline phosphatase levels. Similar increases were noted after the infusion of the low-molecular weight and water-soluble fraction, but not after infusion of the high-molecular weight and ethanol-chloroform-soluble fractions. The whole bile and all fractions except the low-molecular weight fraction contained alkaline phosphatase activity. That a fraction which caused a rise contained no alkaline phosphatase supported the conclusion that the effect on enzyme levels was due to a substance in bile. Since the filter used for bile fractionation retains molecules with a molecular weight greater than 10,000 and as the filtrate contained the active ingredient, its molecular weight must be less than 10,000. Similarly, the stimulating substance must be water soluble. In hepato-biliary diseases this agent, which is produced in the liver and excreted in the bile, may be diffused into the circulation. From there, it would reach the liver where it could induce increased alkaline phosphatase production by all liver cells, whether obstructed or not. Such a mechanism would explain why alkaline phosphatase is often elevated in conditions where the serum bilirubin is normal.

4005 THE ENZYMATIC FORMATION OF BILIRUBIN.

(E.) Schmid, R.; McDonagh, A. F. (Dep. Med., Univ. California, San Francisco). *Ann. NY Acad. Sci.* 244:533-552, 1975.

The enzymatic formation of bilirubin *in vitro* and *in vivo* is reviewed. The biological and chemical systems that convert heme to bile pigment *in vitro* are discussed and three biological systems are described: 1) a light-mitochondrial fraction from the dog placenta; 2) cultured chicken macrophages; and 3) a microsomal enzyme system, heme oxygenase, obtained from spleen, liver, bone marrow, and other tissues. Results of experiments in these systems suggest that the third is responsible for the catabolism of heme *in vivo* and plays a major role in the conversion of hemoglobulin to bilirubin. The following sequence of reactions is probably involved in the formation of bilirubin IX α *in vivo*: *meso*-hydroxylation of heme at the α-bridge; autoxidation of the resulting α-hydroxyheme to carbon monoxide and a biliverdin-iron complex; hydrolysis of the iron complex to biliverdin IXα ; and finally, enzymatic reduction of biliverdin IXα to bilirubin IXα by biliverdin reductase. The mechanism of the initial event, the critical step, is still incompletely understood. *In vitro* studies suggest that heme, bound to a protein, utilizes NADPH and the microsomal electron transport system to reduce oxygen and generate a reactive radical which attacks the heme at the α-bridge to form α-hydroxyheme. In this model, therefore, bound heme catalyzed its own hydroxylation with a binding protein serving as a substrate-specific enzyme. Chemical evidence suggests that the structure of this heme-binding protein is such that the heme is bound in a specific orientation within a crevice and with a strong ligand coordinated to the iron. It is uncertain whether the heme-binding protein, which is equated with the microsomal heme oxygenase discussed under *in vitro* biological systems, is a unique protein specific to the endoplasmic reticulum, or whether other membrane-bound proteins can function in the same capacity.

4006 A MICROPUNCTURE STUDY OF RENAL SALT AND WATER RETENTION IN CHRONIC BILE DUCT OBSTRUCTION.

(E.) Bank, N.; Aynedjian, H. S. (Montefiore Hosp. Med. Cent., Bronx, N.Y.). *J. Clin. Invest.* 55(5):994-1002, 1975.

The mechanism of sodium retention by the kidney of white male Sprague-Dawley rats with common bile duct ligation was studied with micropuncture techniques. Before surgery, an average of 93.2% of the ingested sodium was recovered in the urine over a 3-day observation period. Only 85.6% of the ingested sodium was recovered in the urine 10-14 days after bile duct ligation. This difference of 7.6% represents a positive sodium balance of approximately 142 μEq/day. Measurements of renal blood flow and glomerular filtration rate yielded values that were not different from those in normal control animals. Single nephron filtration rate of surface nephrons was the same in the experimental rats as in the controls. Sodium reabsorption, however, was markedly increased in the proximal convoluted tubule, as well as in segments beyond the proximal convolutions. Single nephron filtration fraction, calculated from measurements of efferent arteriolar and arterial hematocrits, was significantly elevated in the cortical nephrons, even though whole kidney filtration fraction was the same as in normal rats. The calculated protein concentration of cortical peritubular blood was higher in the bile duct-ligated rats than in the normal controls. These observations are consistent with the view that sodium retention is the result of enhanced reabsorption primarily by cortical nephrons. It is suggested that the enhanced reabsorption can be accounted for by relative cortical ischemia due to efferent arteriolar vasoconstriction with the consequent elevation of peritubular colloid oncotic pressure.

4007 BIOSYNTHESIS OF UDP-GLUCOSE BY RAT LIVER MICROSOMES.

(Fr.) Berthillier, G.; Got, R. (Membr. Biochem. Lab., CNRS, Villeurbann, France). *Biochim. Biophys. Acta* 362(2):390-402, 1974.

A microsome fraction was obtained from Wistar rat livers by homogenization and centrifugation, and the supernatant was used to assay the concentration of soluble enzymes. Intermediary metabolites in the biosynthesis of uridine diphosphate glucose (UDP-glucose) were assayed by incubation of a suspension of microsomes in the presence of ^{14}C-glucose followed by analysis by column and thin layer chromatography; and by incubation of microsomes in the presence of glucose 1-phosphate, glucose-6-phosphate, or glucose followed by analysis of the concentration of synthesized UDP-glucose. After 15 min incubation of microsomes in the presence of ^{14}C-glucose, the quantities of glucose-6-phosphate, glucose-1-phosphate, and UDP-glucose formed were 0.96 m, 0.27 m, and 0.06 m, resp. For incubation of microsomes with any of the three precursors, equivalent quantities of UDP-glucose were formed. These results imply that phosphoglucomutase and UTP:D-glucose-1-phosphate uridyl transferase are present in the microsome membranes. The K_m of microsome membrane phosphoglucomutase was found to be 0.26 x 10^{-3} mM for glucose-1,6-diphosphate and 80 x 10^{-3} mM for glucose-1-phosphate at optimum pH and temperature. For soluble phosphoglucomutase, the respective K_m's were 0.4 and 40 x 10^{-3} mM. The K_m of microsome membrane UTP-D-glucose-1-phosphate uridyl transferase was found to be 220 x 10^{-3} mM for UTP and 166 x 10^{-3} mM for glucose-1-phosphate. For soluble UTP-D-glucose-1-phosphate uridyl transferase, the K_m's of UTP were 150 and 200 in and not in the presence of Triton X-100, resp., and for soluble UTP-D-glucose-1-phosphate uridyl transferase, the K_m of glucose-1-phosphate was 100 x 10^{-3} mM. It seems likely that there exists a double pathway, one soluble and one in the membrane, for UDP-glucose synthesis. The absence of accumulation of intermediary metabolites provides further evidence for an organized system of UDP-glucose synthesis by the membrane of rat liver microsomes.

4008 ROLE OF THE LIVER IN COAGULATION AND FIBRINOLYSIS: PATHOPHYSIOLOGICAL AND EXPERIMENTAL ASPECTS OF THE ISOLATED LIVER.

(Fr.) Losito, R. (Dep. Med., Univ. Sherbrooke, Canada). *Union Med. Can.* 103(12):2107-2110, 1974.

Isolated and perfused rat liver was used to study the role of vitamin K, oral anticoagulants, and fibrinolysis in hepatic hemostasis. ^{14}C-Menadione (vitamin K_3) was readily metabolized, and approximately 3/4 of the dose was excreted by both normal and hepatectomized rats. Normal and hepatectomized rats, resp., excreted only 10% and 0.5% of an injected dose of vitamin K_1. This shows that the liver is essential to the metabolism of vitamin K, but not of menadione. It also explains the superiority of vitamin K as an antidote for an overdose of oral anticoagulant. Experiments with ^{14}C-warfarin in the isolated and perfused liver show that it is also excreted more rapidly than vitamin K, although the warfarin activity in the plasma remains essentially intact. The radioactivity in the liver introduced by both warfarin and vitamin K is associated with the microsomes and the supernatant material. Experiments with the fibrinolysin streptokinase show that a certain quantity of plasmin was produced in the perfusate, and different antiplasmins could neither neutralize it nor eliminate it from the liver. Fibrinolytic activity existed in the bile during the entire time of perfusion with streptokinase.

4009 THE EFFECT OF BILE ACID SYNTHESIS ON CHOLESTEROL SECRETION INTO THE BILE.

(E.) Strasberg, S. M.; Ilson, R. G. (Toronto West. Hosp., Canada). *Ann. Surg.* 181(4):458-465, 1975.

Biliary cholesterol and bile acid secretion were studied in three female Rhesus monkeys during the period of increasing bile acid secretion and synthesis occurring 6-10 hr after interruption of the enterohepatic bile acid circulation by cannulation of the common bile duct. The bile acid pool was prelabeled by injection of ^{14}C-cholic acid 24 hr prior to start of the experiment. Bile acid synthesis and phospholipid secretion were increased 3- and 1.5-fold, resp., while cholesterol secretion was decreased 50-60% 40 hr after interruption of the hepatic circulation. Phenobarbital (5 mg/kg/24 hr i.v.) had no effect on the phospholipid secretion rate but did enhance cholesterol secretion and bile acid synthesis. These results suggest that bile acid synthesis influences cholesterol secretion into bile.

4010 ETHANOL - ANTIBIOTIC INTERACTIONS AT HEPATIC LEVEL.

(E.) Grassi, G. G.; Grassi, C. (Inst. Chemother., Univ. Pavia, Italy). *Int. J. Clin. Pharmacol.* 11(3):216-225, 1975.

The effects of acute and chronic ethanol intoxication on blood levels of several antibiotics were studied in fasted male Wistar rats. Acute ethanol intoxication (2 mg/kg 50% ethanol i.v. or 5 mg/kg p.o.) had no effect on blood levels of isoniazid, rifampicin, streptomycin, kanamycin or gentamycin. Although chronic intoxication (5 mg/kg 50% ethanol 5-30 days by gastric intubation) did not alter blood aminoglycoside levels, rifamypicin levels were decreased by 20-50% and isoniazid concentrations were increased 40-80%. Rifampicin impaired hepatic BSP elimination in both acute and chronic experiments with or without alcohol intoxication. Isoniazid affected BSP elimination only in chronically intoxicated and control animals. These studies indicate that ethanol can affect degradation of certain antibiotics and suggest that antibiotic dosage may need modification in alcoholic patients.

4011 ALTERATION BY PHENOBARBITAL AND 3-METHYLCHOLANTHRENE OF FUNCTIONAL AND STRUCTURAL CHANGES IN RAT LIVER DUE TO CARBON TETRACHLORIDE INHALATION.

(E.) Shah, H. C.; Carlson, G. P. (Coll. Pharm., Univ. Rhode Island, Kingston). *J. Pharmacol. Exp. Ther.* 193(1):281-292, 1975.

The effect of carbon tetrachloride (CCl_4) inhalation

(1100 ppm, 30 min) on hepatocyte polyribosome profiles, ^{14}C-leucine incorporation into liver protein and hepatocyte ultrastructure were studied in male Charles River rats pretreated with phenobarbital (50 mg/kg day for 4 days i.p.) or 3-methylcholanthrene (40 mg/kg/day for 2 days i.p.). The liver 9000 x g supernatant polyribosomal pattern was completely disrupted following CCl_4 inhalation in phenobarbital or 3-methyl-cholanthrene pretreated rats and returned to normal after 48 and 24 hr, resp. Incorporation of label into 9000 x g supernatant proteins was inhibited by 58%, 18% and 2% after 0, 24 and 48 hr in phenobarbital-treated rats and by 45% and 13% after 0 and 6 hr in three methycholanthrene-treated animals. The centrilobular hepatocytes of phenobarbital-pretreated rats exposed to CCl_4 showed dilation and vesiculation of cisternea of the rough endoplasmic reticulum as well as dilatation of the nuclear membrane space. Partial recovery occurred within 24 hr and complete recovery was seen 48 hr after exposure to CCl_4. No changes in the nuclear membrane or rough endoplasmic reticulum were observed in CCl_4 3-methylcholanthrene-treated animals. These results are explained by hypothesizing two activation sites for CCl_4 on the reduced NAD-cytochrome P-450 electron transport chain of the liver microsomes.

4012 VITAMIN B_6 METABOLISM IN CHRONIC ALCOHOL ABUSE. THE EFFECT OF ETHANOL OXIDATION ON HEPATIC PYRIDOXAL 5'-PHOSPHATE METABOLISM. *(E.)* Veitch, R. L.; Lumeng, L.; Li, T. K. (Indiana Univ. Sch. Med., Indianapolis). *J. Clin. Invest.* 55(5): 1026-1032, 1975.

The effect of chronic alcohol ingestion on hepatic vitamin B_6 metabolism was studied *in vivo* and *in vitro*. Male Sprague-Dawley rats fed a diet containing ethanol (36% of total calories) and pyridoxine (0.725 μg/ml) for 52 days had a significantly lower ($p < 0.02$) liver pyridoxal phosphate level (7.6 μg/200 mg protein) than animals fed a similar diet containing dextrin maltose instead of ethanol (8.5 μg/200 mg). Liver pyridoxal phosphate levels were also lower in rats fed an ethanol diet for 42 days without vitamin B_6 supplementation (3.0 μg/200 mg protein) than in controls devoid of B_6 supplementation (4.7 μg/200 mg). Perfusion of livers from B_6-sufficient rats with 18 mM ethanol for 3 hr lowered pyridoxal phosphate content by 3.8 μg/200 mg protein ($p<0.02$) compared to increase of 1.0 μg/200 mg in controls. Whereas release of preformed pyridoxal phosphate from perfused B_6-sufficient livers was linear for 3 hr, none was released from perfused B_6-deficient organs. Addition of pyridoxine to the perfusion medium of deficient livers resulted in a striking increase in both pyridoxal phosphate content and its release which could be partially inhibited by 18 mM ethanol. 4-Methylpyrazole (0.24 mM), a competitive inhibitor of liver alcohol dehydrogenase, almost completely abolished the effect of 18 mM ethanol on pyridoxal phosphate release and hepatic pyridoxal phosphate content of perfused organs. These results indicate that the effects of ethanol on hepatic vitamin B_6 metabolism in the rat depend upon its oxidation.

4013 BILE ACIDS. XLV. METABOLISM OF 3β,7α-DIHYDROXY-5α-CHOLESTANOIC ACID IN THE RAT WITH A BILE FISTULA. *(E.)* Mui, M. M.; Elliot, W. H. (St. Louis Univ. Sch. Med., Mo.). *Biochim. Biophys. Acta* 388(1):126-134, 1975.

The metabolism of ^3H-labeled 3β,7α-dihydroxy-5α-cholestanoic acid was studied in three adult male rats with cannulated bile ducts following i.p. administration of 0.34 mg of the potassium salt. Bile collected in the first 24 hr, containing 97% of the administered ^3H was hydrolyzed and the free bile acids were separated by acetic acid partition chromatography. Of the chromatographed tritium, 58% was associated with allochenodeoxycholic acid and 14% with its 3β-isomer; only 5% of the ^3H was found in alcocholic acid and 1% with its 3β-isomer. Less than 5% of the tritium appeared in fractions associated with the substrate or more polar unidentified materials. Thus, this dihydroxy-5α-cholestanoic acid is metabolized in the rat primarily to dihydroxy-5α-cholanic acids, comparable to the metabolism of 3α,7α-dihydroxy-5β-cholestanoic acid in man.

4014 IMMUNOLOGICAL PROPERTIES OF TWO FETUS-SPECIFIC GLOBULINS OF RAT IN EXPERIMENTALLY INDUCED HEPATIC LESIONS. *(E.)* Watanabe, A.; TAketa, K.; Kosaka, K. (Okayama Univ. Med. Sch., Japan). *Acta Med. Okayama* 28(5):321-322, 1974.

Two fetus-specific globulins have been detected in fetal rat serum by using specific antiserum prepared from immunized rabbits. The two globulins, α_1- and α_2-fetoglobulin, migrated on polyacylamide gel discs at rates relative to bromophenol blue of 0.58 and 0.55, resp. α_2-Fetoglobulin was PAS-positive. Both α_1- and α_2-fetoglobulins were detected in amniotic fluid and serum from cadmium chloride-treated rats by immunoelectrophoresis and double-diffusion analysis. Both globulins were detected in serum from adult rats bearing dimethylaminoazobenzene-induced hepatoma. α_2-Fetoglobulin was found in serum from CCl_4, thioacetamide and cadmium chloride-treated adult rats as well as partially hepatectomized animals and rats bearing ascites hepatoma. These results suggest that α_2-fetoglobulin is a sensitive index of tissue injury.

4015 STUDIES ON LIVER REGENERATION. DEOXYRIBONUCLEIC ACID SYNTHESIS IN THE ISOLATED PERFUSED LIVER AFTER IN VITRO AND IN VIVO PARTIAL HEPATECTOMY. *(E.)* Grandjean, C.; Garcia, H. (Univ. Nebraska Med. Cent., Omaha). *Lab. Invest.* 32(4): 552-554, 1975.

DNA synthesis was studied in isolated perfused male Wistar rat livers following *in vitro* partial hepatectomy. Perfused livers were allowed to incorporate ^3H-thymidine for 2 hr beginning 30 min after excision of the median lobe. Specific activity of DNA from perfused regenerating livers was increased 2.2-fold compared to nonregenerating perfused livers. The rate of increase in specific activity was similar to that for *in vivo* partially hepatectomized regenerating organs (2.6-fold). These results suggest that similar regulatory mechanisms for liver regeneration are operative both *in vitro* and *in vivo* and indicate that the liver *per se* may be the source and target of any initiating factor(s) responsible for the phenomenon.

4016 BIOSYNTHESIS OF BLOOD SERUM PROTEINS AND TRANSCRIPTION OF NUCLEAR RNA WITH REGENERATION OF RAT LIVER. *(Ukr.)* Polischuk, A. S.; Korotkoruchko, V. P.; Danko, I. M. (A. V. Palladin Inst. Biochem., Kiev, USSR). *Ukr. Biokhim. Zh.* 46(3):324-327, 1974.

4039 EXPERIMENTAL STUDY OF POSTHEPATIC LYMPHODYNAMICS DURING PORTAL HYPERTENSION. *(It.)* Anfossi, A.; Cavaliere, P.; Adami, G. F.; Tallero, G.; Gianetta, E. (Inst. Gen. Clin. Surg., Surg, Ther., Univ. Genoa, Italy). *Chir. Patol. Sper.* 21(4):274-284, 1973.

4040 ARTERIALIZATION OF THE LIVER IN COMBINATION WITH A PORTACAVAL SHUNT IN THE DOG. *(E.)* Adamsons, R. J.; Arif, S.; Babich, A.; Butt, K.; Lam, A.; Minkowitz, S. (Downstate Med. Cent., State Univ. New York, Brooklyn). *Surg. Gynecol. Obstet.* 140(4):594-600, 1975.

4041 ELECTRON MICROSCOPE EXAMINATION OF THE SITE OF ACID PHOSPHATASE INSIDE THE LYSOSOMES. *(Rus.)* Pokrovskii, A. A.; Krystev, L. P.; Tutelian, V. A.; Boiadzhieva, Zh. K.; Kravchenio, L. V. (Inst. Nutr., Moscow, USSR). *Dokl. Acad. Nauk SSSR* 219(5):1235-1237, 1974.

4042 ELECTROPHORETIC ANALYSIS OF HISTONES IN THE HEPATIC CELL NUCLEI IN CALORIC-DEFICIENT ALBINO RATS. *(Rus.)* Klimenko, A. I.; Khints, R. (Inst. Biol., A.M. Gorky State Univ., Kharkov, USSR). *Vopr. Pitan.* (6):16-19, 1974.

4043 STEROL CARRIER PROTEIN HYPOTHESIS: REQUIREMENT FOR THREE SUBSTRATE-SPECIFIC SOLUBLE PROTEINS IN LIVER CHOLESTEROL BIOSYNTHESIS. *(E.)* Scallen, T. J.; Seetharam, B.; Srikantaiah, M. V.; Hansbury, E.; Lewis, M. K. (Dep. Biochem., Univ. New Mexico, Albuquerque). *Life Sci.* 16(6):853-874, 1975.

4044 REGULATION OF LIPOGENESIS IN ANIMALS. *(Ger.)* Numa, S. (Fac. Med., Kyoto Univ., Japan). *Naturwissenschaften* 62(2):80-86, 1975.

4045 DISTRIBUTION AND TRANSPORT OF [^{14}C] CHOLESTEROL BETWEEN ORGANELLAS OF CELLS IN RAT LIVER. *(Rus.)* Kolomiytseva, I. K.; Kaznacheev, Y. S. (Inst. Biol. Phys., Acad. Sci. USSR, Pushchino). *Ukr. Biokhim. Zh.* 46(6):777-781, 1974.

4046 EFFECT OF FASTING ON THE FREE FATTY ACID CONTENT OF THE LIVER AND KIDNEY IN THE RAT. *(Cz.)* Chorvathova, V; Ondreicka, R.; Ovecka, M. (Res. Inst. Hum. Nutr. Bratislava, Czechoslovakia). *Cz. Gastroent. Vyz.* 28(7):461-466, 1974.

4047 THE INFLUENCE OF A HIGH LEVEL OF DIETARY CORN OIL ON RAT SERUM AND LIVER LIPIDS. *(E.)* Narayan, K. A.; McMullen, J. J.; Butler, D. P.; Wakefield, T.; Calhoun, W. K. (Nutr. Div., US Army Natick Lab., Mass.). *Nutr. Reports Int.* 10(1):25-34, 1974.

4048 SIMPLIFIED METHODS FOR THE EXAMINATION OF LIVER LIPIDS. I. DETERMINATION OF VITAMIN A IN LIVER USING A DIRECT SOLVENT EXTRACTION TECHNIQUE. *(E.)* Bayfield, R. F. (Vet. Res. Stn., Dep. Agric., Glenfield, Australia). *Anal. Biochem.* 64(2):403-413, 1975.

4049 METABOLISM OF ETHANOL. I. HEPATIC OXIDATION OF ETHANOL AND ITS BIOCHEMICAL EFFECT ON THE LIVER. *(Fr.)* Gajdos, A. (Lab. Biochem. Res., Rene Descartes Univ., Paris, France). *Ann. Biol. Clin.* 32(5):405-411, 1974.

4050 EFFECT OF ETHANOL ON UREA SYNTHESIS FROM AMMONIA IN ISOLATED LIVER CELLS FROM FED AND STARVED RATS. *(E.)* Williamson, J. R.; DeLeeuw, G.; Meijer, A. J. (Johnson Res. Found., Univ. Pennsylvania, Philadelphia). *Fed. Proc.* 34(3):573, 1975.

4051 DRUG METABOLISM STUDIES IN ISOLATED RAT HEPATOCYTES. *(E.)* Billings, R. E.; Ashmore, J.; Wagle, S. R.; McMahon, R. E. (Indiana Univ. Sch. Med., Indianapolis). *Fed. Proc.* 34(3):727, 1975.

4052 EVIDENCE LINKING SINGLET OXYGEN FORMATION WITH DRUG METABOLISM AND LIPID PEROXIDATION IN RAT LIVER MICROSOMES. *(E.)* King, M.; Lai, E.; McCay, P. B. (Oklahoma Med. Res. Found., Oklahoma City). *Fed. Proc.* 34(3):622, 1975.

4053 INFLUENCE OF PARTIAL DEHYRATION ON THE QUANTITATIVE CYTOARCHITECTURE OF RAT HEPATOCYTES (A CYTOPHOTOMETRIC AND MORPHOMETRIC STUDY). *(Ger.)* Riede, U. N.; Kreutzer, W.; Robausch, T.; Kiefer, G.; Sandritter, W. (Pathol. Inst., Univ. Freiburg; Germany). *Beitr. Pathol.* 153(4):379-394, 1974.

4054 ARE ATYPICAL LIVER MITOCHONDRIA SPECIAL ADAPTIVE FORMS? III. PARACRYSTALLINE INCLUSIONS IN THE INTRACRISTAL SPACE. *(Ger.)* Riede, U. N.; Nobmann, E. (Pathol. Inst., Univ. Freiburg, Germany). *Beitr. Pathol.* 153(4):319-329, 1974.

4055 EFFECT OF RENAL MICROSOMES AND RENAL LYSOSOMES ON IN VITRO HEPATIC FATTY ACID SYNTHESIS. *(E.)* Haven, G. T.; Nguyen, T. T.; Krzemien, J. R.; Thuy, L. P. (Coll. Med., Univ. Nebraska, Omaha). *Res. Commun. Chem Pathol. Pharmacol.* 10(3): 473-490, 1975.

4056 THE DEVELOPMENT OF KINETIC PARAMETERS OF HEPATIC DRUG-METABOLIZING ENZYMES IN PERINATAL RATS. *(E.)* Bell, J. U.; Ecobichon, D. J. (Dep. Pharmacol., Dalhousie Univ., Halifax, Canada). *Can. J. Biochem.* 53(4):433-437, 1975.

4057 INHIBITION OF NADPH OXIDATION AND OXIDATIVE METABOLISM OF DRUGS IN LIVER MICROSOMES BY ZINC. *(E.)* Chvapil, M; Sipes, I. G.; Ludwig, J. C.; Halladay, S. C. (Univ. Arizona Med. Sch., Tucson). *Biochem. Pharmacol.* 24(8):917-919, 1975.

4058 CADMIUM POTENTIATION OF DRUG RESPONSE - ROLE OF THE LIVER. *(E.)* Johnston, R. E.; Miya, T. S.; Schnell, R. C. (Sch. Pharm. Pharm. Sci., Purdue Univ., West Lafayette, Ind.). *Biochem. Pharmacol.* 24(8):877-881, 1975.

4059 EFFECT OF SILYBIN ON THE HEPATIC MICROSOMAL DRUG-METABOLISING ENZYME SYSTEM IN THE RAT. *(E.)* Down, W. H.; Chasseaud, L. F.; Grundy, R. K. (Huntingdon Res. Cent., England). *Arzneim. Forsch.* 24(12):1986-1988, 1974.

4060 PROLIFERATION KINETICS OF BILE DUCT EPITHELIA IN THE REGENERATING MOUSE LIVER AFTER CCl_4 POISONING. *(Ger.)* Gerhard, H.; Schultze, B.; Maurer, W. (Inst. Med. Radiol., Univ. Wurzburg, Germany). *Virchows Arch.* [*Zellpathol.*] 17(3):213-227, 1975.

4061 HEXOKINASE ISOZYME PATTERN IN CCl_4-INJURED RAT LIVER. *(E.)* Ueda, M.; Taketa, K.; Kosaka, K. (Okayama Univ. Med. Sch., Japan). *Clin. Chim. Acta.* 60(1):77-84, 1975.

4062 DETECTION OF EARLY METABOLITES IN RAT LIVER AFTER ADMINISTRATION OF CCl_4 AND $CBrCl_3$. *(E.)* Bini, A.; Vecchi, G.; Vivoli, G.; Vannini, V.; Cessi, C. (Inst. Gen. Pathol., Univ. Modena, Italy). *Pharmacol. Res. Commun.* 7(2):143-149, 1975.

4063 SYNTHESIS OF RAT LIVER RNA UNDER CONDITIONS OF PROTEIN SYNTHESIS INHIBITION BY CYCLOHEXIMIDE. *(Ukr.)* Todorov, I. N.; Halkin, A. P.; Kornyushyna, T. V.; Yuhai, N. V.; Hovze, Y. H. (Inst. Mol. Biol. Genet., Acad. Sci. Ukr. SSR, Kiev, USSR). *Ukr. Biokhim. Zh.* 46(4):431-437, 1974.

4064 INFLUENCE OF LEAD-OVERLOAD ON THE QUANTITATIVE CYTOARCHITECTURE OF JUVENILE RAT HEPATOCYTES. *(Gen.)* Riede, U. N.; Rasser, Y. M.; Rohr, H. P. (Inst. Pathol., Univ. Basel, Switzerland). *Beitr. Pathol.* 152(4):383-394, 1974.

4065 GLUCOCORTICOID INDUCED LESIONS IN RAT LIVERS. *(E.)* Kim, Y. S.; Choi, B. H.; Kim, Y. (St. Louis Univ. Sch. Med., Mo.). *Exp. Mol. Pathol.* 22(2):260-270, 1975.

4066 IN VIVO DETOXIFICATION OF ENDOTOXIN BY MOUSE LIVER. *(E.)* Rippe, D. F.; Soltas, J. G.; Berry, L. J. (Dep. Microbiol., Univ. Texas, Austin). *J. Reticuloendothel. Soc.* 16(3):175-183, 1974.

4067 LIVER LEVELS OF α-GLYCEROPHOSPHATE, GLYCEROPHOSPHATE DEHYDROGENASE AND ACETYL-CoA CARBOXYLASE DURING PHENOBARBITAL INDUCTION. *(E.)* Depierre, J. W.; Ernster, L. (Dep. Biochem., Arrhenius Lab., Univ. Stockholm, Sweden). *FEBS Lett.* 52(2)L 240-241, 1975.

4068 FACTORS INVOLVED IN INCREASED PROTEIN SYNTHESIS IN LIVER MICROSOMES AFTER ADMINISTRATION OF DDT. *(E.)* Cappon, I. D.; Nicholls, D. M. (Dep. Biol., York Univ., Toronto, Canada). *Pestic. Biochem. Physiol.* 5(2):109-118, 1975.

4069 INFLUENCE OF PARENTERAL ZINC AND ACTINOMYCIN D ON TISSUE ZINC UPTAKE AND THE SYNTHESIS OF A ZINC-BINDING PROTEIN. *(E.)* Richards, M. P.; Cousins, R. J. (Dep. Nutr., Cook Coll., Rutgers Univ., New Brunswick, N.J.). *Bioinorg. Chem.* 4(3):215-224, 1975.

4070 2-AMINOACETAMIDO-N-ARYLBENZAMIDES AS POTENTIAL CHOLERETIC AND ANTIFIBRILLATORY AGENTS. *(E.)* Bonola, G.; Magistretti, M. J.; Setnikar, I.; Massarani, E. (Res. Div., Recordati S.p. A., Milan, Italy). *Eur. J. Med Chem.* 7121(9):639-640, 1974.

4071 BIOLOGICAL POTENCY OF ORGANIC SELENIUM COMPOUNDS: VI. ALIPHATIC SELENINIC ACIDS AND CARBOXYSELENINIC ACIDS. *(E.)* Schwarz, K.; Fredga, A. (VA Hosp., Long Beach, Calif.). *Bioinorg. Chem.* 4(3):235-243, 1975.

4072 CHANGES IN METABOLISM OF ETHANOLAMINE AND ITS DERIVATIVES IN LIVER DURING FASTING. *(E.)* Haines, D. S. M.; Derksen, D. H. (Victoria Hosp., London, Canada). *Can. J. Biochem.* 53:51-56, 1975.

4073 CELLULAR REACTION OF HEPATIC STROMA IN VARIOUS REGIMENS OF PATHOGENIC ACTION. *(Rus.)* Popova, I. V. (I. M. Sechenov 1st Moscow Med. Inst., USSR). *Biull. Eksp. Biol. Med.* 78(12):102-105, 1974.

4074 THE EFFECT OF Mg^{++} IONS ON LIVER PRESERVATION. *(Ger.)* Lie, T. S.; Nakano, H.; Haupt, H.; Ebata, H.; Rommelsheim, K. (Surg. Clin., Univ. Bonn, Germany). *Bruns Beitr. Klin. Chir.* 221(8):643-646, 1974.

4075 THE ALTERATIONS IN CoA CONTENT IN ORGANS OF YOUNG RATS AFTER ADMINISTRATION OF PANTOTHENATE DERIVATIVES. *(Rus.)* Rosanov, A. Y.; Agafonova, N. Y.; Yakovlev, V. A.; Kopelevich, V. M.; Yevdokimova, G. S. (I. I. Mechnikov State Univ., Odessa, USSR). *Vopr. Med. Khim.* 20(4):363-367, 1974.

4076 ACCUMULATION OF MALONYLDIALDEHYDE IN ISOLATED RAT LIVER. *(Rus.)* Panchenko, L. F.; Gerasimov, A. M.; Nozdrachova, L. I.; Kariakina, G. A. (N. I. Pirogov 2nd Moscow Med. Inst., USSR). *Vopr. Med. Khim.* 20(3):321-324, 1974.

4077 THE EFFECT OF HYDROCORTISONE AND ACUTE HYPOXIA ON GLUCONEOGENESIS OF RAT LIVER. *(Rus.)* Postupaev, V. V.; Litonyan, Z. M. (Khabarovsk Med. Inst., USSR). *Biull. Eksp. Biol. Med.* 78 (12):19-24, 1974.

4078 EFFECT OF VITAMIN E ON INTENSITY OF METHIONINE TRANSFORMATION IN RAT LIVER. *(Ukr.)* Shtutman, T. M.; Biber, H. O. (A. V. Palladin Inst. Biochem., Kiev, USSR). *Ukr. Biokhim. Zh.* 46(2): 192-196, 1974.

4079 CYTOFLUOROMETRIC STUDY OF THE TWO GLYCOGEN FRACTIONS IN THE RAT LIVER CELLS. *(Rus.)* Kudryavtseva, M. V.; Kudryavtsev, B. N.; Rosanov, Y. M. (Inst. Cytol., Acad. Sci. USSR, Leningrad). *Cytologiia* 16(7):851-858, 1974.

4080 CYCLIC NUCLEOTIDES AND GLUCONEOGENESIS BY RAT LIVER CELLS. *(E.)* Fain, J. N.; Tolbert, M. E. M.; Pointer, R. H.; Butcher, F. R.; Arnold, A. (Div. Biol. Med. Sci., Brown Univ., Providence, R.I.). *Metabolism* 24(3):395-408, 1975.

4081 SEX DIFFERENCES IN THE EFFECTS OF ETHIONINE ON RNA AND PROTEIN SYNTHESIS IN SWISS MICE. *(E.)* Berry, D. E.; Friedman, M. A. (Med. Col. Virginia, Richmond). *Fed. Proc.* 34(3):872, 1975.

4082 INFLUENCE OF DL-ETHIONINE ON THE ACCUMULATION AND SUBCELLULAR DISTRIBUTION OF COPPER IN THE LIVER OF RATS INJECTED WITH COPPER. *(E.)* Balevska, P. S. (Inst. Physiol., Bulgarian Acad. Sci., Sofia). *C. R. Acad. Sci. (Bulg.)* 28(1): 125-127, 1975.

4083 NEONATAL IMPRINTING AND THE TURNOVER OF MICROSOMAL CYTOCHROME P-450 IN RAT LIVER. *(E.)* Levin, W.; Ryan, D.; Kuntzman, R.; Conney, A. H. (Dep. Biochem. Drug Metab., Hoffmann-La Roche, Inc., Nutley, N.J.). *Mol. Pharmacol.* 11(2):190-200, 1975.

4084 NOVEL LIVER MICROSOMAL ENZYME INHIBITORS. *(E.)* Israili, Z. H.; Black, N. B.; Dayton, P. G. (Dep. Med., Emory Univ., Atlanta, Ga.). *Fed. Proc.* 34(3):784, 1975.

4085 STUDIES ON ACUTE PHASE PROTEINS OF RAT SERUM. V. EFFECT OF INDUCED INFLAMMATION ON THE SYNTHESIS OF ALBUMIN AND α_1-ACID GLYCOPROTEIN BY LIVER SLICES. *(E.)* Jamieson, J. C.; Morrison, K. E.; Molasky, D.; Turchen, B. (Dep. Chem., Univ. Manitoba, Winnipeg, Canada). *Can. J. Biochem.* 53(4): 401-414, 1975.

4086 THIAMINE INCREASES THE SPECIFIC ACTIVITY OF HUMAN LIVER BRANCHED CHAIN α-KETOACID DEHYDROGENASE. *(E.)* Danner, D. J.; Davidson, E. D.; Elsas II, L. J. (Emory Univ. Sch. Med., Atlanta, Ga.). *Nature* 254(5500):529-530, 1975.

4087 INCORPORATION OF AMINO ACIDS INTO PROTEINS OF RAT LIVER SUBCELLULAR FRACTIONS UNDER THE EFFECT OF MULTIPLE INJECTIONS OF ACTH AND ACTH COMBINATION WITH RNA. *(Ukr.)* Hermaniuk, Ia. L.; Sydorenko, D. S. (Kiev Sci. Res. Inst. Endocrin. Metabol., Min. Public Health Ukr. SSR, Kiev, USSR). *Ukr. Biokhim. Zh.* 46(4):438-440, 1974.

4088 EFFECTS OF FASTING ON THE ACTIVITY OF CYTOSOL FACTORS ENGAGED IN PROTEIN BIOSYNTHESIS IN MOUSE HEPATOCYTES. *(E.)* Gamulin, S.; Norman, M. R. (King's Coll. Hosp. Med. Sch., London, England). *Nutr. Metabol.* 17(2):121-126, 1974.

4089 EFFECT OF MULTIPLE INJECTIONS OF ACTH, ALONE AND IN COMBINATION WITH RNA, ON PROTEIN METABOLISM IN THE LIVER, SPLEEN, AND MUSCLES OF ALBINO RATS. *(Ukr.)* Hermaniuk, Ia. L.; Sydorenko, D. S.; Bohdan, I. P. (Kiev. Res. Inst. Endocrinol. Metab., USSR). *Dopovidi Akad. Nauk Ukr. RSR [B]* (11):1036-1039, 1974.

4090 INFLUENCE EXERTED BY VITAMIN A ON THE ACTIVITY OF PHENYLALANINE-4-HYDROXYLASE AND TYROSINE-AMINOTRANSFERASE IN THE RAT LIVER. *(Rus.)* Fedurov, V. V.; Terentieva, V. G. (Kiev Med. Inst., USSR). *Vopr. Pitan.* (6):12-16, 1974.

4091 INDUCTION AND INHIBITION OF TYROSINE AMINOTRANSFERASE IN MOUSE AND RAT LIVER BY VITAMIN B_6 ANTAGONISTS AND BY INHIBITORS OF PYRIDOXAL-5'-PHOSPHATE ENZYMES. *(Rus.)* Bukin, Iu. V.; Matveeval, A. A. (Inst. Exp. Clin. Oncol., Moscow, USSR). *Biokhimiia* 39(6):1146-1156, 1974.

4092 BREAKDOWN OF ALBUMIN IN THE SUBCELLULAR COMPARTMENTS OF THE LIVER. *(Ger.)* Massarrat, S.; Siai, D. J. (Med. Polyclin., Phillips Univ., Marburg/Lahn, Germany). *Res. Exp. Med. (Berl.)* 164(1):49-58, 1974.

4093 EVIDENCE FOR A UDP-GLUCOSE RECEPTOR IN THE MICROSOMAL MEMBRANES OF RAT HEPATOCYTES. *(Fr.)* Frot-Coutaz, J.; Berthillier, G.; Got, R. (Lab. Biochem., Univ. Claude Bernard, Lyon, France). *Febs Lett.* 52(1):81-84, 1975.

4094 EVOLUTION AND CONTROL OF CARBAMYL PHOSPHATE SYNTHETASE AND ORNITHINE TRANSCARBAMYLASE IN DEVELOPING FETAL RAT LIVER. *(Fr.)* Gautier, C.; Husson, A.; Vaillant, R. (Lab. Endocrinol., Univ. Rouen, France). *Experientia* 31(1):125-126, 1975.

4095 REGULATION OF PYRUVATE DEHYDROGENASE INTERCONVERSION IN ISOLATED HEPATOCYTES BY THE MITOCHONDRIAL ATP/ADP RATIO. *(E.)* Siess, E. A.; Wieland, O. H. (Schwabing Hosp., Munich, Germany). *Febs Lett.* 52(2):226-230, 1975.

4096 CORTICOSTERONE CONTENT IN NUCLEI OF THE HEART, BRAIN, AND LIVER OF ALBINO RATS AT DIFFERENT AGES. *(Ukr.)* Nesterenko, H. A. (Inst. Biol., Kharkov State Univ., USSR). *Dopovidi Akad. Nauk Ukr. RSR* [B] (11):1042-1044, 1974.

4097 METABOLISM OF GLUCOCORTICOIDS AND THEIR TRANSPORT-RESERVE FORMS IN ISOLATED PERFUSED LIVER. *(Ukr.)* Treshchynskyi, A. I.; Mozhaev, H. A.; Shlapak, I. P. (Inst. Postgrad. Training Physicians, Kiev, USSR). *Ukr. Biokhim. Zh.* 46(2):188-191, 1974.

4098 INFLUENCE OF THE LIVER ON THE PRE- AND POSTHEPATIC CONCENTRATIONS OF PLASMA HISTAMINE IN HUMAN SUBJECTS. *(Ger.)* Stopik, D.; Berger, H. G.; Bittner, R.; Brauer, D.; Fiedler, A. (Westend. Clin., Free Univ. Berlin, Germany). *Klin. Wochenschr.* 52(14):696-698, 1974.

4099 PROLACTIN RECEPTORS IN RAT LIVER: POSSIBLE INDUCTION BY PROLACTIN. *(E.)* Posner, B. I.; Kelly, P. A.; Friesen, H. G. (McGill Univ. Clin., Montreal, Canada). *Science* 188(4183):57-59, 1975.

4100 A METHOD FOR PERFUSION OF THE CANINE LIVER IN VIVO VIA THE HEPATIC ARTERY WITH BLOOD OF A CONTROLLED GAS CONTENT. *(E.)* Andrews, W. H. H.; Bradley, D. J. (R. Free Hosp. Sch. Med., London, England). *J. Physiol. (Lond.)* 246(2):5P-6P, 1975.

4101 EFFECT OF THE AMMONIA TOLERANCE TEST ON ISOLATED PERFUSED SWINE LIVER. *(Ger.)* Hirner, A.; Haring, R.; Stallkamp, B; Tung, L.C.; Waldschmidt, J. (Steglitz Clin., Free Univ. Berlin, Germany). *Z. Exp. Chir.* 7(3):179-187, 1974.

4102 SELECTIVE IN SITU PERFUSION OF THE CANINE LIVER. *(Ger.)* Duca, S. (Surg. Clin. III., Cluj, Rumania). *Bruns Beitr. Klin. Chir.* 221(8):647-654, 1974.

4103 THE PATHOPHYSIOLOGY OF ACUTE RENAL INSUFFICIENCY ASSOCIATED WITH HEPATOBILIARY DISEASE. *(Ger.)* Peschl, L. (Kaiserin Elisabeth Hosp., Vienna, Austria). *Acta Med. Aust.* 1(5):144-150, 1974.

4104 EXPERIMENTAL LYMPHOSTASIS OF THE LIVER. *(Ger.)* Lie, T. S.; Seifert, G.; Fasske, E.; Nakano, H.; Ebata, H.; Bartsch, G. (Surg. Clin. Polyclin., Univ. Bonn, Germany). *Leber Magen Darm* 4(6):313-316, 1974.

4105 THE INHIBITION OF THE UPTAKE OF ^{3}H-THYMIDINE INTO LIVER DNA BY THE INTRAPORTAL INFUSION OF FRESH SERUM AFTER PARTIAL HEPATECTOMY IN THE RAT. *(E.)* Bradbrook, R. A.; Newcombe, R. G.; Thatcher, J.; Blumgart, L. H. (Welsh Natl. Sch. Med., Cardiff). *Eur. Surg. Res.* 6(6):364-374, 1974

4106 EXPERIMENTAL HEPATOGRAPHY WITH IOPHENDYLATE. *(Rus.)* Sviridov, N. K. (Moscow Res. Inst. Roentgenol. Radiol., USSR). *Eksp. Khir. Anestesiol.* (5):53-55, 1974.

4107 HEPATOPROTECTIVE ACTION OF DICARBOXYLIC AMINO ACIDS AND AMIDES. *(Rus.)* Maliugin E. F.; Khokhlov, A. P.; Terentieva, V. B.; Gogiberidze, G. V. (N.I. Pirogov 2nd Moscow Med. Inst., USSR). *Farmakol. Toksikol.* 37(6):703-704, 1974.

4108 THERAPEUTIC ATTEMPT IN EXPERIMENTAL HEPATITIS. *(Ser.)* Stern, P.; Gmaz-Nikulin, E. (Inst. Pharmacol., Fac. Med., Sarajevo, Yugoslavia). *Acta Med. Iugosl.* 28(5):447-451, 1974.

4109 CHANGE IN FUNCTION OF OVARIES AND ADRENAL GLANDS IN RATS WITH EXPERIMENTAL TOXIC HEPATITIS. *(Rus.)* Khominskaia, Z. B. (Inst. Pediatr., Gynecol., Obstet., Kiev, USSR). *Fiziol. Zh.* 20(6):747-751, 1974.

4110 DISRUPTION OF THE HETEROPHAGE FUNCTION OF LIVER LYSOSOMES IN RATS SUFFERING FROM ACUTE AND CHRONIC TOXIC HEPATITIS. *(Rus.)* Korolenko, T. A.; Titova, V. G.; Kondakova, A. E. (Novasibirsk Med. Inst., USSR). *Farmakol. Toksikol.* 37(6):725-727, 1974.

4111 BIOCHEMICAL AND MORPHOLOGICAL CHANGES IN THE LIVER AND BLOOD SERUM IN EXPERIMENTAL LIVER FAILURE. *(Rus.)* Rusakov, V. I.; Alimova, E. K.; Lokshin, L. S.; Pustovalova, L. M.; Dzarokhokhov, K. I. (Rostov Med. Inst., USSR). *Eksp. Khir. Anesteziol.* (6):41-44, 1974.

4112 CHANGE IN SUBMICROSCOPIC ORGANIZATION OF HEPATOCYTES, AND IN HEPATOCYTE AND CATION CONTENTS UNDER EXPERIMENTAL RACHITES IN RATS. *(Ukr.)* Mynonova, V. M.; Khomutovsky, O. A. (A. V. Palladin Inst. Biochem., Kiev, USSR). *Ukr. Biokhim. Zh.* 46(5):635-638, 1974.

4113 CONTENT AND DISTRIBUTION OF UBIQUINONE AND UBICHROMENOL IN UNSAPONIFIABLE FRACTION OF LIVER SUBCELLULAR STRUCTURES IN NORMAL RATS AND RATS WITH HYPOVITAMINOSIS A AND E. *(Ukr.)* Chernukhina, L. O.; Donchenko, G. V.; Kovalenko, V. M. (A. V. Palladin Inst. Biochem., Kiev, USSR). *Ukr. Biokhim. Zh.* 46(4):514-518, 1974.

4114 CHANGES OF SPECIFIC ACTIVIY AND SYNTHESIZING ACTIVITY OF CATALASE IN ACATALASEMIA MOUSE LIVER. *(E.)* Ogata, M.; Takagi, M.; Ogata, K.; Tomokuni, K.; Mizugaki, J.; Takahara, S. (Okayama Univ. Med. Sch., Japan). *Tohoku J. Exp. Med.* 114 (4):349-354, 1974.

4115 GALACTOSAMINE-"HEPATITIS" IN RATS WITH DIFFERENT PHAGOCYTIC ACTIVITY OF LIVER RES. *(E.)* Rasenack, U.; Grun, M.; Liehr, H. (Dep. Int. Med., Univ. Wurzburg, Germany). *Acta Hepatogastroenterol. (Stuttg.)* 22(1):29-35, 1975.

4116 EXCRETION OF BILIRUBIN IN THE GASTROINTESTINAL TRACT AND ITS CONVERSION INTO UROBILINOGEN. THE ENTEROHEPATIC CIRCULATION AND EXCRETION OF UROBILINOGEN. DIRECT TRANSPORT BETWEEN THE BLOOD AND GASTROINTESTINAL TRACT. *(It.)* Coltorti, M.; Di Somone, A. (1st Fac. Med. Surg., Univ. Naples, Italy). *Fegato* 19(2):167-204, 1973.

4117 TRANSPORT OF BILIRUBIN FROM BLOOD PLASMA TO HEPATOCYTES. *(It.)* Frezza, M.; Tiribelli, C. (Inst. Spec. Med. Pathol., Univ. Trieste, Italy). *Fegato* 19(2):109-117, 1973.

4118 CHANGES IN BILIRUBIN IN THE HEPATOCYTE AND IN EXTRAHEPATIC SITES. *(It.)* Michelazzi, L.; Nanni, G.; Marinari, U. M.; Casu, A. (Inst. Gen. Pathol., Univ. Genoa, Italy). *Fegato* 19(2): 119-144, 1973.

4119 INTERACTIONS BETWEEN BILIRUBIN AND COMPONENTS OF THE HEPATOCYTE MEMBRANE. *(It.)* Casu, A.; Pala, V.; Marinari, U. M.; Nanni, G. (Inst. Gen. Pathol., Univ. Genoa, Italy). *Fegato* 19(2): 145-159, 1973.

4120 INTERACTIONS BETWEEN THE EXCRETION OF BENZYLPENICILLIN, BILIRUBIN AND BSP IN THE BILE: EFFECT OF SOME LIVER FRACTIONS AND THEIR CONSTITUENTS. *(It.)* Paroli, E.; Samueli, F.; Valeri, P. (Dep. Pharmacol., Univ. Rome, Italy). *Fegato* 19(2):293-300, 1973.

4121 SUBCELLULAR CARBOXYLESTERASE ACTIVITY AND THE HEPATIC TRANSPORT OF BILIRUBIN. *(It.)* Burlina, A.; Boccato, P.; Sorgato, K.; Galzigna, L. (Gen. Provinc. Hosp., Conegliano, Italy). *Fegato* 19(2):161-166, 1973.

4122 INTERACTION OF BILIRUBIN WITH HUMAN ERYTHROCYTE MEMBRANE. *(E.)* Kapoor, C. L. (Cent. Drug Res. Inst., Lucknow, India). *Curr. Sci.* 44(3):82-84, 1975.

SECRETION AND METABOLISM

Intestine

4149 ENZYMES OF FRUCTOSE METABOLISM IN HUMAN SMALL INTESTINE MUCOSA. *(E.)* Heinz, F.; Schlegel, F.; Krause, P. H. (Med. Coll. Hannover, Germany). *Enzyme* 19(2):93-101, 1975.

The enzyme activities involved in fructose metabolism were measured in human intestine mucosa obtained 2 hr post mortem. Mucosa of the following gut sections were used: duodenum, jejunum, jejunum in the region of the flexura duodenojejunalis, distal jejunum, ileum middle region and ileum in the region of the valvula ileo cecalis. Only samples which showed a normal histological picture, where autolyzed cells were absent and no pathological changes could be observed, were chosen. Ketohexokinase, aldolase, alcohol dehydrogenases NAD- and NADP-dependent were found in all gut sections. The activity of aldehyde dehydrogenase was low in all sections tested. Triokinase could be found only in the duodenum and jejunum region and was absent in the ileum. Glycerate kinase was not present in the human intestine mucosa. Thus, the activities of all the enzymes involved in fructose metabolism were found in human small intestine mucosa, except D-glycerate kinase. There was, however, a broad standard deviation among the results, which may be due to differences in the nutritional state of the donors.

4150 EFFECT OF FAT FEEDING ON COMPLEX LIPID SYNTHESIS IN HAMSTER INTESTINE. *(E.)* Mansbach, II, C. M. (VA Hosp., Durham, N.C.). *Gastroenterology* 68(4):708-714, 1975.

Three enzymes engaged in complex lipid synthesis, diglyceride acyltransferase, cholinephosphotransferase, and lysolecithin acyltransferase, were studied in nonfasting hamster intestinal mucosa to determine if these enzymes were responsive to dietary fat supplementation. Male golden Syrian hamsters eating a fat-supplemented (corn oil) diet were compared to those eating a low fat (chow) diet. The diets were offered *ad libitum* for 1 week prior to death. The chow-fed group had gained an average of 4 g body weight and the fat-supplemented group, 5 g. The intestine was divided into four segments, pylorus to cecum, and the mucosa of each segment was scraped to yield a villous tip and crypt preparation. In the villous tips, fat supplementation had no effect on diglyceride acyltransferase and lysolecithin acyltransferase specific activity in the most proximal intestine. Both enzymes demonstrated increased activity in villous tips in response to fat feeding in the distal 3/4 of the gut. Cholinephosphotransferase activity was increased by fat feeding throughout the intestine in villous tips. Diglyceride acyltransferase and lysolecithin acyltransferase activity was greater in villous tips as compared to crypts. Cholinephosphotransferase activity was the same in crypts as in villous tips. Lysolecithin transferase was more responsive to fat feeding than was cholinephosphotransferase. It is claimed that these data lend support to the thesis that the lysolecithin acyltransferase pathway provides the lecithin associated with intestinal lipoprotein formation. Of four microsomal enzymes not related to lipid metabolism, only one, NADPH-cytochrome c reductase, was affected by fat feeding suggesting that the microsomal enzyme response to fat feeding was relatively specific.

4151 THE EFFECT OF ACUTE ETHANOL TREATMENT ON LIPID-REESTERIFYING ENZYMES OF THE RAT SMALL BOWEL. *(E.)* Rodgers, J. B.; O'Brien, R. J. (Albany Med. Coll., N.Y.). *Am. J. Dig. Dis.* 20(4): 354-358, 1975.

The acute effects of intraduodenal administration of ethanol (5 g/kg) on intestinal activities of lipid-reesterifying and disaccharidase enzymes of the small bowel were studied in male Sprague-Dawley rats. Animals were infused intraduodenally with ethanol or isocaloric glucose for 5 hr at 2.4 ml/hr. Animals were fasted overnight, sacrificed, and the small intestine distal to the ligament of Treitz removed and divided into the jejunal and ileal segments. Mucosal samples of each segment were scraped, homogenized, and assayed for enzyme activity. Acyl-coenzyme A(CoA):monoglyceride acyltransferase, acyl-CoA synthetase (acid:CoA ligase), sucrase, and lactase assays were performed on jejunal samples; acyl-CoA synthetase assay was performed on ileal samples. Ethanol administration produced greater activities of the lipid-reesterifying enzymes in the jejunum than did glucose administration. Ileal specific activity of acyl-CoA synthetase was also increased in the ethanol group. No effect of ethanol on jejunal disaccharadase enzyme activities was seen. It is concluded that ethanol, given acutely, has a specific stimulating effect on intestinal enzymes involved in lipid absorption.

4152 ILEAL HCO_3 SECRETION: RELATIONSHIP TO Na AND Cl TRANSPORT AND EFFECT OF THEOPHYL-

LINE. *(E.)* Sheerin, H. E.; Field, M. (Harvard Med. Sch., Boston, Mass.). *Am. J. Physiol.* 228(4):1065-1074, 1975.

Interrelationships among Na, Cl, and HCO_3 transport processes were examined in short-circuited New Zealand white, male rabbit ileal mucosa. Na and Cl fluxes at different serosal HCO_3 concentrations were determined either in paired experiments on tissues from the same animal or in nonpaired but randomized experiments. As serosal HCO_3 concentration was increased from 10 to 50 mM (pH from 7.1 to 7.8), net Na absorption decreased from 4.6 to 0.3 $\mu Eq/hr/cm^2$, net Cl flux changed from absorption of 0.9 to secretion of 0.9 and a net HCO_3 secretion of 3.0 developed. A similar change in net Cl flux was also observed when serosal CO_2 was altered at constant HCO_3 concentration. In Cl-free SO_4-Ringer, serosal alkalinization produced net HCO_3 secretion which was not significantly less than that observed in Cl-containing Ringer. Theophylline caused secretory changes in net Na and Cl fluxes at both 10 and 50 mM serosal HCO_3 concentrations. Theophylline did not alter net HCO_3 flux in Cl-Ringer but increased net HCO_3 flux in SO_4-Ringer. Total direct current conductance was decreased by both serosal alkalinization and theophylline. Short-circuit current was consistently increased by theophylline but not by serosal alkalinization. These results indicate that ileal ion transport is regulated in part by serosal pH and/or HCO_3 concentration and that resulting changes in Cl and HCO_3 transport are coupled 1:1 with changes in Na transport. It is also concluded that HCO_3 secretion does not require the presence of Cl in the bathing medium.

4153 DIGESTION AND ABSORPTION OF THE CONSTITUENTS OF CONCENTRATED MILK PRODUCTS WITH SPECIAL REFERENCE TO THE EFFECT OF INCREASED QUANTITIES OF LACTOSE. *(Pol.)* Cieslakowa, D.; Palaszewska, M.; Ziemlanski, S. (Inst. Nutr. Food Prod., Warsaw, Poland). *Przegl. Lek.* 31(2):328-333, 1974.

A total of 420 male Wistar rats (6 and 10 weeks old) were fed diets containing various amounts of lactose (from 3 to 15%). The following parameters were studied: digestion of protein and fat; the rate at which protein, fat, and lactose passed into the duodenum; the absorption of these nutrients in small intestine; and concentrations of α-amino nitrogen, fat, and glucose in the portal and cardiac blood. With increasing amounts of dietary lactose the rate of gastric emptying decreased, especially during the first 30 minutes. Increasing dietary lactose from 3% to 12% had no effect on digestion and absorption of nitrogen compounds from the small intestine, but 15% lactose slightly decreased protein digestion and decreased digestion and absorption of fat. Increasing dietary lactose from 3% to 15% caused a corresponding increase in rate at which liberated glucose was digested and absorbed.

4154 ACUTE AND CHRONIC EFFECTS OF ETHANOL ON INTESTINAL LIPID METABOLISM. *(E.)* Baraona, E.; Pirola, R. C.; Lieber, C. S. (VA Hosp., Bronx, N. Y.). *Biochim. Biophys. Acta* 388(1):19-28, 1975.

The effects of both the addition *in vitro* of various ethanol concentrations and the previous *in vivo* administration of ethanol on the ability of intestinal slices to oxidize fatty acids and to synthesize triacylglycerols were assessed in CD male rats. The rats were pair-fed a synthetic liquids diet containing 18% of the total calories as protein, 35% as fat, 11% as carbohydrate, and 36% either as ethanol or additional carbohydrate (control diet) for 3-4 weeks. Animals were sacrificed and the small intestine, from the angle of Treitz to the ileo-cecal junction, was stripped from the mesentery. Segments of the intestine from the proximal 20 cm of jejunum and from the ileum (between 30 and 10 cm proximal to the cecum) either were sliced in rings for the metabolic studies *in vitro* or were used for the enzyme assays. The addition of ethanol to the incubation medium in concentrations likely to be achieved in the upper jejunum after moderate drinking inhibited both palmitate and acetate oxidation, CO_2 production and triacylglycerol synthesis, but enhanced the esterification of fatty acid with ethanol. The concentrations required for the inhibitory effect were much higher than those needed to saturate enzyme systems known to participate in ethanol oxidation. *In vivo* administration of ethanol-containing diets produced persistent changes of the intestinal slices with respect to fatty acid oxidation and triacylglycerol synthesis. Acute intragastric administration of ethanol (3 g/kg) 1 hr prior to sacrifice, inhibited both processes in slices obtained from the jejunum, but not in those derived from the ileum. Chronic ethalol feeding increased the ability for fatty acid oxidation and triacylglycerol synthesis both in the jejunum and in the ileum. This stimulatory effect was associated with significant enhancement of palmitoyl-coenzyme A synthetase activity, suggesting increased fatty acid activation. These findings suggest that the high concentrations of ethanol to which the small intestine is exposed during drinking inhibit fatty acid oxidation and esterification to triacylglycerols apparently as a consequence of a direct damaging effect of alcohol. It is further suggested that prolonged ethanol administration promotes functional and structural changes which result in an increased capacity for fatty acid oxidation and triacylglycerol synthesis.

4155 INFLUENCE OF SECRETIN AND PENTAGASTRIN ON THE CIRCADIAN RHYTHM OF CELL PROLIFERATION IN THE INTESTINAL MUCOSA IN RATS. *(E.)* Pansu, D.; Berard, A.; Dechelette, M. A.; Lambert, R. (INSERM, Edouard Herriot Hosp., Lyon, France). *Digestion* 11 (3/4):266-274, 1974.

The effects of pentagastrin and secretin on DNA synthesis in rat jejunal mucosa were studied. Wistar rats were fasted 24 hr and given 25 μg/100 g pentagastrin or 3.5 U/100 g secretin, and sacrificed after 0, 4, 8, 12, 16, 20, and 24 hr. Controls were given saline. For the pentagastrin 6 rats were paired with 6 controls; for secretin, 7 rats paired with 6 separate controls. For DNA labeling, rats were injected i. p. with 70 Ci/100 g $[^3H]$ thymidine 30 min before killing. Histoautoradiography was done on sections of intestine 10 cm distal to the ligament of Treitz. Labeling index was the percentage of labeled nuclei counted in the proliferative compartment (the first 30 cells in the crypt) and mitotic index was the percentage of nuclei in the mitotic state determined for 1800 cells/crypt. After pentagastrin injection, labeling index was 31.73 at time 0, rose to 46.7 at 12 hr, and stabilized at this level until 24 hr later. In contrast, controls had a labeling index of 31.73 at time 0 which rose to 45.0 at 12 hr and returned to 36.45 at 24 hr. Treated cells had significantly higher indices than controls at 20 and 24 hr. The increased number of labeled cells in comparison to controls was in the upper part of the crypt. The mitotic index after injection rose from 7.31 at time 0 to 10.26, 24 hr later, similar to the control values of 7.30 at time 0 and 10.36 after 24 hr. After secretin injection the nocturnal increase in labeling index disappeared, there being no significant difference between values at time 0 (33.25) and 24 hr (38.10). The mitotic index was 7.83 at time 0 and remained steady, thus becoming significantly lower than control values after 24 hr (10.52). The decreased number of labeled cells in comparison to the controls was in the lower part of the crypt. It is concluded that pentagastrin has a stimulating effect on the circadian rhythm of cell renewal, increasing the labeling index and increasing the proliferative zone, while secretin has an inhibitory effect, decreasing both labeling and mitotic indices.

GENERAL

4164 EFFECTS OF 400 R WHOLE-BODY X-IRRADIATION ON 5-HYDROXYTRYPTAMINE CONTENT OF THE RAT GASTROINTESTINAL TRACT. *(E.)* Penttila, A.; Kormano, M.; Ahonen, A. (Dep. Forensic Med., Univ. Helsinki, Finland). *Strahlentherapie* 149(4):426-437, 1975.

The effects of a single 400 r whole-body dose of x-irradiation on the regional 5-hydroxytryptamine content of the gastrointestinal tract of adult and young male Sprague-Dawley rats were studied from 4 hr to 40 days after irradiation using comparative chemical and morphological methods. The 5-hydroxytryptamine content of tissue pieces was determined in µg/whole organ, and per wet weight of tissue as well as per tissue protein using spectrophotofluorometry. After a single dose of radiation the total 5-hydroxytryptamine content of the stomach and intestinal tract was significantly lower in the irradiated than in the control rats 4 hr and 1 and 2 days after irradiation. The total amine content of the gastrointestinal tract returned to normal 5 days after irradiation and remained constant thereafter. Some differences were found between the various regions. Some minor morphological changes were seen in enterochromaffin cells 1 and 2 days after irradiation but not later. The effects of irradiation of the gastrointestinal tissues were stronger in young rats, in which no complete recovery of 5-hydroxytryptamine occurred within 45 days. The results support the view that irradiation exerts a direct damaging effect on the gastrointestinal 5-hydroxytryptamine storage, which is associated with liberation of 5-hydroxytryptamine from amine-containing cells. It is concluded that the duration of the effect varies with age and intestinal segment concerned and that the maturation of the animals affords some protection against its effects.

4165 MICROCIRCULATION OF THE NORMAL AND INFLAMED CANINE PANCREAS. *(E.)* Schiller, W. R.; Anderson, M. C. (Med. Coll. Ohio, Toledo). *Ann. Surg.* 181(4):466-470, 1975.

The microcirculation of the pancreas of five normal dogs and the inflamed gland of experimental pancreatitis induced in another five dogs was studied using an intraarterial injection of Microfil, a silicon rubber compound with a particle size of 1-3 μ. Laparotomy was performed through a midline incision upon 10 anesthetized adult mongrel dogs. In the five control animals, Microfil was injected into the cranial pancreaticoduodenal artery. The pancreas and adjacent duodenum were immediately excised between clamps and stored in a refrigerator overnight to allow polymerization of the Microfil. In the other five, pancreatitis was induced by a transduodenal retrograde injection of 150,000 U trypsin in 15 ml saline into the major pancreatic duct. The animals were re-operated 24 hr later, Microfil injected according to the same procedure as for the 3 controls, and specimens obtained and processed. Specimens were examined with a dissecting microscope and photographed. Duodenal vasculature and lobular vessels of the pancreas were studied as were those supplying the duct. Interlobular vessels were well visualized in the normal pancreas and intralobular vessels formed a fine reticular pattern throughout the cleared lobules. A complex network of vessels was observed in the pancreatic duct, apparently derived from the interlobular vessels. Intraductal trypsin injection produced focal areas of pancreatitis associated with edema, poor vascular filling and spastic changes of the lobular vessels. Extravasation of Microfil, although not apparent on normal specimens, was prominent in inflamed specimens and suggested vascular weakness and disruption. Pancreatic lobules adjacent to inflammatory areas showed definite evidence of dilatation. The inflamed pancreatic ducts were markedly edematous, thickened, and showed incomplete vascular filling. When the duodenum adjacent to the pancreatitis was injected with Microfil, edema and vasoconstriction were especially prominent in the duodenal muscular layer. It is suggested that the compromise of parenchymal circulation in combination with enzyme extravasation into the gland parenchyma may contribute to increased severity of the pancreatic inflammation; a re-distribution of pancreatic blood flow occurred with hyperperfusion of minimally involved areas and stasis in the inflamed pancreas. The changes in the duodenal microcirculation suggest that the abnormal gastrointestinal motility associated with pancreatitis may result in part from an altered circulation in the duodenal muscularis.

4166 THE EFFECT OF ELECTRICAL STIMULATION OF THE CELIAC GANGLION ON PANCREATIC BLOOD FLOW. *(Fr.)* Varga, B.; Folly, G.; Papp, M. (Inst. Exp. Med., Budapest, Hungary). *Lyon Chir.* 70(3): 168-170, 1974.

Male dogs averaging 16 kg were subjected to electrical stimulation of the left celiac ganglion with 2 min bursts of rectangular electrical impulses (20 impulses/sec at 2.5, 5, and 10 V). The pancreatic blood flow was measured by heated thermocouples and recorded on a fluorograph, while the arterial pressure was measured in a femoral artery. The stimulus amplitude was varied in a random sequence, and the corresponding blood flow was recorded. Electrical stimulation raised the blood pressure and decreased the pancreatic blood flow in proportion to the amplitude of the stimulus. When the pancreatic blood flow was increased by injecting dehydrocholic acid (4 mg/Kg/min i.v.), it dropped even more significantly when an electrical impulse was applied. It is suggested that during acute pancreatitis the reflex contraction of pancreatic blood vessels aggravates the disease. When laparatomy is performed, the celiac ganglion should be amply infiltrated with a local anesthetic to prevent spastic contraction of the pancreatic vessels.

4167 BACTERIAL DEGRADATION OF β-MURICHOLIC ACID IN THE RAT. *(Fr.)* van Heijenoort, Y.; Sacquet, E.; Riottot, M. (Lab. Germfree Anim., CNRS, Gif-sur-Yvette, France). *Nutr. Metab.* 17(2):65-73, 1974.

Bacterial degradation of β-muricholic acid was studied by thin layer chromatographic analysis of the feces of two holoxenic male Fischer rats, aged 3 months, which had been injected in the stomach with an excess of β-muricholic-4-^{14}C acid (12.25 mg, containing 0.44 μCi). By the second day after injection, almost 95% of the radioactivity had been excreted and was distributed among various degradation products of β-muricholic acid, principally hyodeoxycholate. When the hyodeoxycholate zone of the chromatograms was eluted and rechromatographed, 91% of the radioactivity originally injected was found at the level of the control methyl hyodeoxycholate. The remaining radioactivity was distributed at the levels of two unknown substances, four methyl esters of acids, particularly 3α, 6β-dihydroxy-5β-methyl cholanoate, and the chromic oxidation product of methyl β-muricholate. *In vitro* incubation of 5 mg β-muricholic acid-4-^{14}C with a homogenate of rat cecum resulted in degradation of only 22% of the β-muricholic acid. The radioactivity appeared on the chromatograms mainly at the level of an unknown substance and at the levels of two methyl cholanoates. There was no significant radioactivity at the levels of hyodeoxycholate and 3α, 6β-dihydroxy-5β-methyl cholanoate. These results contrast with observations on axenic rats in which β-muricholic acid is the main bile acid. The degradation pathway of β-muricholic acid by intestinal flora remains obscure.

4168 ARTERIOVENOUS INTESTINAL COMMUNICATIONS IN SHOCK. EXPERIMENTAL STUDY USING TAGGED MICROSPHERES. *(E.)* Androulakis, J.; Androulakis, G.; Vezeridis, M.; Kyriakou, K. (Aretaeion Hosp., Athens, Greece). *Int. Surg.* 60(4):206-208, 1975.

Polystyrene microspheres, 25 μ in diameter labeled with ^{141}Ce and ^{85}Sr were used to study the influence of oligemic shock on arteriovenous anastomoses of the small intestine mucosa of five dogs and five white New Zealand rabbits. One ml of [^{141}Ce] microsphere solution was injected into a catheter in the superior mesenteric artery. The intraaortic pressure was recorded through a catheter connected to an electromanometer. Oligemic shock was created by gradual peripheral arterial bleeding in 60-100 min, until blood pressure dropped to 20-30 mm Hg, and was maintained at this level for at least 30 min. At this stage, the ^{85}Sr solution was injected. Following injection of the second microsphere solution, the animal was sacrificed, using an i.v. dose of KCl. Radioactivity was measured in a specimen of small bowel corresponding to the injected branch of the superior mesenteric artery and one from the liver, as well as in the syringes before and after microsphere injection. No radioactivity was detected in the liver either before or during oligemic shock. Most of the radioactivity was retained in the intestinal mucosa. These data suggest that the microspheres did not pass through the microcirculation of the intestine, indicating that there are no arteriovenous anastomoses in the intestinal mucosa, or that if they do exist they are less than 25 μ in diameter. The last possibility is considered the more probable since there are many hemodynamic and metabolic indications for the existence of shunts and their opening during shock.

DIAGNOSTIC PROCEDURES

4186 PREOPERATIVE DIAGNOSIS OF THE MECKEL'S DIVERTICULUM BY SEQUENTIAL 99m TECHNETIUM PERTECHNETATE SCANNING. *(E.)* Lee, H. K.; Schwartz, I. S.; Nipper, T.; Gichon, G.; Beck, A. R. (City Hosp. Cent. Elmhurst, N.Y.). *Mt. Sinai J. Med NY* 42(2):136-141, 1975.

A 28-month-old female presented with a 2 hr history of passing bloody stools. There was no evidence of abdominal pain, nausea, or other symptoms, but there had been a 6 day episode of bloody stools at the age of 18 months. During the first 12 hr of observation no further bloody stools were passed. Twenty-four hr after admission an abdominal scan was performed. The stomach was emptied by nasogastric tube and 50 mg sodium iodide was injected i.v. to block background activity. The infant was placed supine under the scanning apparatus and 1.5 mCi of ^{99}m Tcpertechnetate was injected through a left leg vein. Sequential scintiphotos were taken for the following 4 3/4 hr. These demonstrated a round focal area of increased activity in the right mid-abdomen, simultaneously visualized with stomach activity. Meckel's diverticulum was diagnosed and confirmed on surgery. The diverticulum-bearing segment of ileum was resected, and the appendix removed. Histologic study showed normal ileal mucosa lining the segment, and numerous gastric parietal acid-secreting cells in the diverticulum that had caused extensive ulceration of the ileo-diverticular junction. Simultaneous scanning of the specimen showed a high concentration of technetium in the parietal cell portion. The appendix appeared normal. It is concluded that sequential scanning is useful in diagnosis of Meckel's diverticulum, and makes possible simultaneous visualization of the diverticulum and stomach activity.

4187 A NEW HYDROGEN ION TELEMETRY TECHNIQUE FOR EVALUATING GASTROESOPHAGEAL REFLUX. *(E.)* Brooks, J.; Kia, D.; Meguid, M.; Lewicki, A.; Membreno, A.; Culebras, J. (Peter Bent Brigham Hosp., Harvard Med. Sch., Boston, Mass.). *Surg. Gynecol. Obstet.* 140(5):749-955, 1975.

A new pH capsule telemetry technique was used to measure the pH fluxes in the upper part of the gastrointestinal tract in normal volunteers, symptomatic patients, and in those with hiatal herniorrgraphy during the preoperative and postoperative periods. The telemetry system consists of a pH-measuring radio capsule which measures the H^+ activity of the surrounding medium to ± 0.2 pH unit in a range of pH 1-8. The reference electrode is self-contained. The capsule is small (0.8 x 7.9 mm) and contains a radiotransmitter which emits a signal determined by the pH of the surrounding medium. This signal is converted to a linear graph on a strip chart recorder. The capsule was swallowed with ease and with minimal discomfort by a fasting patient. The mean basal pH range in the esophagus 5 cm above the gastroesophageal junction in fasting normal persons was 7.5. A significant drop occurred when the capsule entered the empty fasting stomach (3.8) and dropped further to 1.8 with the addition of 240 ml HCl. The mean basal esophageal pH in a group of patients with symptoms of reflux was 7.6. A significant, sharp and sudden pH drop to 2.6 occurred on advancing the capsule into the fasting stomach. On returning the capsule to a position 5 cm above the gastroesophageal junction, the pH stabilized to 7.0 which differed significantly from the basal esophageal pH in this group. In these patients, acid reflux into the lower part of the esophagus was consistently induced by this maneuver. In six patients with hiatal hernia, no reflux was noted after a transabdominal Nissen fundoplication or a Belsey-type buttress procedure. In two patients who underwent an Allison repair without fundioplication, reflux persisted postoperatively. It is concluded that this pH capsule telemetry is easy to perform on an ambulatory basis and allows an accurate and reproducible determination of the presence or absence of esophageal reflux in patients with and without hiatal hernia. Its correlation with symptomatic reflux is higher than that found with a conventional gastrointestinal series examination.

4188 OPERATIVE BIOPSY OF THE PANCREAS. *(E.)* George, P.; Brown, C.; Gilchrist, J. (R. Free. Hosp., London, England). *Br. J. Surg.* 62(4):280-283, 1975.

A retrospective study was undertaken of 47 patients (19-84 yr) who had open pancreatic biopsies during the course of a laparotomy to determine whether the procedure was safe and whether worthwhile information was obtained. The most common indication for biopsy (35 cases) was histological confirmation of a suspected carcinoma. Pancreatic biopsies were also taken from patients in whom the nature of the pancreatic pathology was in doubt and from patients who had preoperative investigations suggesting pancreatic disease but who had a macroscopically normal pancreas at operation. The anterior surface of the pancreas was exposed by opening the lesser sac. The biopsy was taken from the most superficial and firmest part of the lesion using a tenotomy knife; a small pyramid (0.3 x 0.3 x 0.3 cm) of tissue was removed. The exposed raw area was covered with either a piece of Oxycel or omentum, lightly held in place by two chromic catgut sutures. In this series of patients none of the postoperative complications could be attributed to the biopsy. It is claimed that the procedure is safe using the technique described provided that the biopsy is kept as superficial as possible and care is taken not to biopsy the region of the main pancreatic duct. It is concluded that the pancreatic biopsy is of value. If carcinoma is found, then there is unequivocal proof of the lesion. If chronic pancreatitis or a normal pancreas is found, then there is contributory evidence of a non-malignant condition. It is suggested that in the vast majority of cases (91% in this group) reliable information will be obtained.

4189 EMERGENCY PERITONEOSCOPY. *(Fr.)* Rachail, M.; Coralle, J.; Maurel, G. (Univ. Hosp. Cent. Grenoble, France). *Arch. Fr. Mal. App. Dig.* 63(2):103-108, 1974.

Emergency peritoneoscopies were performed on 80 patients: 14 with abdominal trauma (of the diaphragm, spleen, liver, pancreas, abdominal wall) or hemoperitoneum and 66 with acute abdominal diseases (cholecystitis, pancreatitis, choliangitis, appendicitis, intestinal obstruction, malignant tumors, tuberculosis, sigmoiditis). The procedure was well tolerated in all but 1 patient whose small intestine was punctured, and led to a correct diagnoses in 71 of 80 cases. It is recommended as a safe and efficient diagnostic procedure in cases of acute abdomen, even in comatose patients.

4190 THE TREHALOSE TOLERANCE TEST IN THE INVESTIGATION OF INTESTINAL ABSORPTION IN PATIENTS ON INTERMITTENT HEMODIALYSIS.

(Ger.) Pointner, H.; Flegel, U.; Bayer, P. M.; Schmidt, P. (1st Med. Clin., Univ. Vienna, Austria). *Wien. Klin. Wochenschr.* 86(22):691-693, 1974.

The trehalose test for intestinal malabsorption was performed on 9 uremic patients receiving intermittent hemodialysis. None had any signs of malabsorption. They were given 50 g α-D-trehalose one day before their weekly dialysis. One week later they received the same amount of glucose. The blood sugar content was checked at regular intervals from 0 to 120 minutes after each test, and a trehalose absorption index (TAI) was computed from these data. The same procedure was applied to a group of 5 normal patients. No significant difference in the TAI was found between the 2 groups. Thus the trehalose tolerance test is valuable in the diagnosis of malabsorption in patients with renal insufficiency.

4191 A SIMPLE METHOD FOR CALCULATING HEPATIC BILIRUBIN CLEARANCE: ITS APPLICATION IN PATIENTS WITH GILBERT'S SYNDROME.

(Ger.) Kutz, K.; Egger, G.; Bachofen, H.; Preisig, R. (Inst. Clin. Pharmacol., Univ. Bern, Switzerland). *Helv. Med. Acta* 37(5/6):386-387, 1974.

A simple method for the calculation of the hepatic bilirubin clearance in the diagnosis of Gilbert's syndrome is described. The bilirubin production in mg/day is calculated as the product of blood volume, hemoglobin concentration, daily rate of hemolysis, equalling 100/age of erythrocytes, and a factor 36.3. The age of the erythrocytes was determined by the ^{51}Cr method. This method, also requiring the determination of the serum bilirubin concentration, permits differentiation between patients with Gilbert's syndrome and normal subjects, as well as patients with increased hemolysis.

4192 IN VIVO STAINING OF GASTRIC MUCOSA: ITS APPLICATION TO ENDOSCOPIC DIAGNOSIS OF INTESTINAL METAPLASIA.

(E.) Ida, K.; Hashimoto, Y.; Kawai, K. (Murakami Mem. Hosp., Gifu, Japan). *Endoscopy* 7(1):18-24, 1975.

In vivo staining of the human gastric mucosa was examined using the indirect dye scattering method with p.o. methylene blue. Endoscopic examination following methylene blue administration revealed complete staining of the gastric mucosa within 2-3 min. Postgastrectomy examination of dye-stained specimens indicated that the dye was taken up by the surface epithelial layer of the gastric mucosa. The stained region was generally located in the pyloric gland area, and areas of intestinal metaplasia were selectively stained when present. Staining was observed in 105 (65.6%) of 160 patients, with staining frequency by disease as follows: gastric polyp, 93%; gastric ulcer, 55%; gastric ulcer scar, 77%; gastric carcinoma, 50%. These values increased with age. Ninety percent of the stained region was of the antral type, the antral region being primarily stained; the remaining 10% was of the intermediate type in which the staining ranged as far as the upper boundary of the pyloric gland area. The most common staining pattern (83%) was one in which granules were stained; in the remaining cases, small depressed regions between the granules were stained. The results suggest that granular-antral staining is the most commonly observed pattern. This *in vivo* staining method offers promise as a means of improving the endoscopic diagnosis of intestinal metaplasia, gastric cancer, and benign atypical epithelium.

4193 EVALUATION OF WHOLE AND PURIFIED HYDATID FLUID ANTIGENS IN THE DIAGNOSIS OF HUMAN HYDATIDOSIS BY THE IMMUNOELECTROPHORESIS TEST.

(E.) Varela-Diaz, V. M.; Guisantes, J. A.; Ricardes, M. I. Yarzabal, L. A.; Coltorti, E. A. (Pan Am. Zoonoses Cent., World Health Org., Ramos Mejia, Argentina). *Am. J. Trop. Med. Hyg.* 24(2):298-303, 1975.

The efficacy of whole sheep hydatid cyst fluid (WHF) and purified hydatid fluid antigen (PHF) in the diagnosis of human hydatid disease was evaluated with the immunoelectrophoresis (IEP) test. Both antigens were tested with preoperative and postoperative sera from 75 patients with hyatid disease, sera from 41 patients with other parasites, sera from 41 patients with nonparasitic diseases, and sera from 20 healthy donors. Among the hydatid sera, 86.7% yielded positive results with the PHF antigens, 70.7% yielded positive results with the WHF antigen, and 13.3% yielded negative results with both antigens. None of the non-hydatid sera reacted positively with the WHF antigen, but 28% of the sera from patients with other parasitic and non-parasitic diseases yielded positive results with the purified antigen. Among preoperative hydatid patients, the *Echinococcus granulosus*-specific arc 5 criterion of positivity was superior to the number of arcs in the diagnosis of hydatidosis with the WHF antigen. However, the number of bands other than arc 5 may be of value in the diagnosis of hydatid disease by the IEP test in cases where this diagnostic arc is absent.

4194 THE EARLY DIAGNOSIS OF BILIARY ATRESIA.

(E.) Kimura, S. (Iwate Med. Coll., Morioka, Japan). *Prog. Pediatr. Surg.* 6:91-112, 1974.

Thirty-four cases of biliary atresia and 12 cases of neonatal hepatitis were analyzed with regard to differential diagnosis. Seven cases of neonatal hepatitis and 22 patients with biliary atresia were admitted before the age of ten weeks. About 35% of the atresia cases while only about 25% of the hepatitis cases had jaundice present from birth. Marked progressive hepatomegaly was a characteristic of both groups, but a decrease in liver size before 3 months of age indicated hepatitis. Liver consistency was always harder in cases of atresia. Routine liver function tests were of little value. Serial determinations of total serum bilirubin levels showed increases in all but two of 10 cases of atresia, while hepatitis tended to show a fluctuating or gradually descending curve. High levels of alkaline phosphatase were found only in atresia during critical periods. Elevation of serum leucine aminopeptidase activity was more frequent in atresia than in hepatitis. The Rose Bengal test resulted in excretion of less than 6% ^{131}I in most of the atresia cases, and over 9% in most of the hepatitis cases during the 72 hr after i.v. administration. However, contamination of the feces with urine, despite precautions, reduced reliability. Serial scintigrams of the liver at 1, 24, 48 and 72 hr after injection of the ^{131}I proved to be more reliable. Shadows of the liver and kidneys could be clearly seen in atresia but not in hepatitis. Biopsy showed that portal fibrosis, ductular proliferation, and cholestasis in the ductular system and liver cells were more marked in biliary atresia. It is concluded that serial total bilirubin tests, leucine aminopeptidase activity tests, histologic examination of the liver, and most importantly the ^{131}I Rose Bengal excretion test with scintigraphy of the liver are most valuable in the differential diagnosis of these two conditions.

4195 EVALUATION OF BARIUM AND GASTROGRAFIN AS CONTRAST MEDIA FOR THE DIAGNOSIS OF ESOPHAGEAL RUPTURES OR PERFORATIONS.

(E.) Vessal, K.; Montali, R. J.; Larson, S. M.; Chaffee, V.; James, A. E., Jr. (Pahlavi Univ. Med. Sch., Shiraz, Iran). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):307-319, 1975.

The effects of barium sulfate and meglumine diatrizoate, alone and in combination with bacterial cultures of pooled human mouth flora, on the feline mediastinum were evaluated. Catheters were passed through the abdominal esophagus into the mediastinum of adult domestic short-haired cats. Commercial barium, sterile barium sulfate, meglumine diatrizoate, and/or flora were injected into the mediastinum *via* the catheters and the animals were monitored clinically and with chest roentgenograms for 2-90 days. All cats injected with the commercial barium had well-localized white, chalky deposits within the paraesophageal mediastinal tissue at the sites of inection, and some animals had similar foci scattered throughout the visceral and intercostal pleura. Granulomatous inflammation including vascular tissue and fibrosis was observed, the extent of such leions generally increasing with time; these lesions were free of bacterial, fungal, and protozoal organisms. Similar lesions were observed in the ats injected with sterile barium sulfate and in hose injected with barium plus flora. Most of he cats injected with meglumine diatrizoate alone showed no pathologic changes, although 1 had a minimal inflammatory reaction; most of the cats injected with meglumine diatrizoate plus flor had mild inflammatory reactions. Flora alone produced mildly to moderately acute mediastinal inflammation. In cultures of human flora, the commercial barium inhibited growth by 70%, while the sterile barium sulfate inhibited growth by 55%. The data suggest that the water-soluble contrast media cause no significant histologic reactions in the mediastinum. Although barium causes granuloma formation, its superior physical properties make it as the contrast agent of choice with difficult clinical problems relating to esophageal rupture or perforation.

4196 VALUE OF THE ENDOSCOPIC DYING METHOD WITH METHYLENBLUE.

(E.) Deyhle, P.; Tschen, H. (Dep. Inn. Med., Univ. Zurich, Switzerland). *Endoscopy* 7(1):24-26, 1975.

The specificity of the endoscopic methylene blue dye method described by Suzuki *et al.* was examined using 75 patients in whom diagnostic evidence had already been obtained. All of the carcinomas in these patients were homogeneously stained a deep blue, all stained areas yielding carcinomatous tissue on biopsy. The extent of the carcinoma was also more accurately defined after staining as compared with the results obtained with normal endoscopy. None of 12 benign ulcers took up the dye at their margins, and an adenomatous gastric polyp also failed to stain. Seventeen of 50 stomachs which appeared normal on normal endoscopy showed a stippled staining pattern with methylene blue which was readily distinguishable from the staining patterns of the carcinomas. Most of these areas showed intestinal metaplasia, although mucous-secreting cells were also stained. In 1 instance, an intestinal metaplasia failed to stain. In some cases, fragments of mucus adhering to the stomach wall took up the stain; in these instances, washing with water removed the dye. The results suggest that this dye method should be used where endoscopy points to suspected early cancer or to a carcinomatous ulcer, but where biopsy samples provide no confirmation. The method is, however, too time-consuming to find acceptance for routine endoscopy.

4197 DIFFERENTIATION OF PANCREATITIS FROM COMMON BILE DUCT OBSTRUCTION WITH HYPERAMYLASEMIA.

(E.) Lesser, P. B.; Warshaw, A. L. (Harvard Med. Sch., Boston, Mass.). *Gastroenterology* 68(4):636-641, 1975.

Patients with abdominal pain and hyperamylasemia (37) were evaluated to determine which elements of the history, physical examination, and laboratory tests are most useful in the differentiation of pancreatitis from common bile duct obstruction with hyperamylasemia. The patients studied had a surgical or definite radiological diagnosis of acute pancreatitis (13 patients), common duct stone without pancreatitis (9 patients), or common duct stone with acute pancreatitis (15 patients). The single facet of the history with discriminatory value was the location of the pain: patients with common duct stone had right upper quadrant pain more frequently than patients with common duct stone and acute pancreatitis or acute pancreatitis alone. Laboratory tests alone, serum amylase, urinary amylase, serum lipase, serum transaminase, bilirubin, and serum calcium were not reliable in the discrimination of pancreatitis from bile duct obstruction. The renal clearance of amylase, expressed as a percentage of creatinine clearance, clearly separated patients with acute pancreatitis and those with common duct stone and acute pancreatitis from patients with common duct stone without pancreatitis with no overlap of values. The mean amylase:creatinine clearance ratio for acute pancreatitis (9.8) and for common duct stone with acute pancreatitis (8.9) was significantly higher than for common duct stone without pancreatitis (3.2) and controls (3.1). In this study, an amylase:creatinine clearance ratio of greater than 5.5% indicated clinically important pancreatitis, and, conversely, a lower value indicated the absence of significant pancreatitis. It is suggested that this index would be useful in guiding the selection of patients for safe, early common duct exploration.

4198 GALACTOSE RETENTION: AN ALTERNATIVE TO THE BROMSULPHTHALEIN TEST.

(E.) Sinniah, D. (R. Victoria Hosp., Belfast, Northern Ireland). *Singapore Med. J.* 15(4):273-275, 1974.

A study of galactose retention was performed in 12 control subjects and 38 patients to determine if the galactose and BSP retention tests give equivalent information. The patient group included eight with obstructive jaundice, five with cancer metastases in the liver, eight with infectious hepatitis, and 17 with cirrhosis. The galactose test was carried out after an 8-12 hr fast. Galactose (350 mg/kg) was administered i.v. as a sterile 25% solution over a period not exceeding 3 min. When half the volume had been given, a stopwatch was started and 30 min later, 0.1 ml of blood was taken from a finger tip for galactose determination. In 15 of 17 cirrhotic patients, a 45 min BSP retention test was carried out immediately after the galactose test. The galactose retention was normal in 87.5% of patients with biliary obstruction and four single cases of mucocele of the gall bladder, the Budd-Chiari syndrome, duodenal ulceration, and polycythemia. The mean galactose retention in the group of patients with obstructive jaundice was 31.6 mg/100 ml; in the group with liver metastases, 84.0 mg/100 ml; in the hepatitis patients, 48.2 mg/100 ml; and in the cirrhotic patients, 88.8 mg/100 ml. There was good correlation between the results of the galactose and the BSP retention tests in the 15 cirrhotic patients. It is suggested that the galactose test has a place in the group of liver function tests because it can be used as an aid in differentiating between parenchymatous and obstructive jaundice and also as a substitute for the BSP test in the presence of jaundice, or where there is a history of allergy to BSP.

4199 PERCUTANEOUS ASPIRATION BIOPSY OF THE PANCREAS UNDER ULTRASONIC GUIDANCE.

(E.) Smith, E. H.; Bartrum, R. J., Jr.; Chang, Y. C.; D'Orsi, C. J.; Lokich, J.; Abbruzzese, A.; Dantono, J. (Harvard Med. Sch., Boston, Mass.). *N. Engl. J. Med.* 292(16):825-828, 1975.

Percutaneous aspiration biopsy of the pancreas under ultrasonic guidance was evaluated in 7 patients with suspected pancreatic tumors. In each case, the pancreatic mass was localized with a standard ultrasonic transducer. The standard transducer was then replaced with a modified instrument equipped with a central canal through which a 19-gauge needle was passed and directed along the path of the sound beam. A 23-gauge needle attached to an aspiration syringe was then directed through the 19-gauge needle and passed into the mass. In 5 cases, the aspirates provided cytologically conclusive evidence of carcinoma, and in a sixth patient the aspirate was strongly suggestive of neoplasia. None of the patients experienced subjective discomfort either during or after the percutaneous puncture procedure, and there was no objective clinical evidence of noteworthy patient injury. Although fine-needle biopsy is not expected to prolong life in patients with pancreatic tumors, it does eliminate the need for more complicated, uncomfortable, and hazardous diagnostic procedures. In many cases, exploratory surgery may be obviated. This method therefore appears to offer considerable value in overall patient management.

4200 RADIOISOTOPE SCINTIGRAPHY IN DIAGNOSIS OF BARRETT'S ESOPHAGUS.

(E.) Berquist, T. H.; Nolan, N. G.; Stephens, D. H.; Carlson, H. C. (Mayo Clin., Rochester, Minn.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):401-411, 1975.

A new approach to the diagnosis of Barrett's esophagus is described. Patients suspected of having Barrett's esophagus were fasted and given 5 mCi Tc^{99m} pertechnetate i.v. Scintigraphic imaging was performed with the patient standing after 30 and 60 min. After the scan, the patients were given barium p.o. and a roentgenogram was taken in the upright position. In the normal person, the isotope is intensely concentrated by the stomach, there is a lack of radionuclide uptake by the esophagus, and evidence of activity is seen in the cardiac pool. In Barrett's esophagus, the roentgenogram shows an esophageal hiatal hernia and a stricture of the mid-esophagus. Activity is taken up by the stomach and esophagus to a level corresponding to that of the stricture. In 5 men with Barrett's esophagus, the diagnosis was made on the basis of an abnormal uptake of the isotope by the lower esophagus. In 1 additional patient who had a rare variant of Barrett's esophagus, Barrett's ulcer, the radioisotope was concentrated in the areas of esophageal ulceration. In each instance, the diagnosis was confirmed by tissue biopsy. Three patients with esophageal conditions other than Barrett's esophagus or Barrett's ulcer were also studied; scintigrams showed no esophageal uptake of pertechnetate and biopsies confirmed the absence of gastric mucosa in the esophagus. Scanning of the esophagus with Tc^{99m} pertechnetate appears to be useful in making or excluding a diagnosis of Barrett's esophagus and promises to be useful in studying the etiology of the disorder.

4201 ENDOSCOPIC EXAMINATIONS IN SOME GASTROINTESTINAL DISEASES IN CHILDREN. *(Rus.)* Mazurin, A. V.; Barchunov, B. N.; Zaprudnov, A. M.; Barchunova, N. N.; Miroshnichenko, V. A.; Prokopova, I. GASTROINTESTINAL DISEASES

ESOPHAGUS

4299 EFFECT OF INCREASED INTRAABDOMINAL PRESSURE ON LOWER ESOPHAGEAL SPHINCTER PRESSURE. *(E.)* Dodds, W. J.; Hogan, W. J.; Miller, W. N.; Stef, J. J.; Arndorfer, R. C.; Lydon, S. B. (Med. Coll. Wisconsin, Milwaukee). *Am. J. Dig. Dis.* 20(4):298-308. 1975.

Lower esophageal sphincter (LES) responses to increased intra-abdominal pressure were evaluated in 20 normal subjects (mean age 22.6 yr) and 35 patients (mean age 47.3 yr) with reflux esophagitis. Intra-abdominal and intragastric pressure were increased by abdominal compression, the Valsalva maneuver, and leg raising. Changes in LES pressure were measured by station and rapid pull-through techniques, using a catheter system capable of radially recording pressure. Abdominal compression and Valsalva increased LES pressure in normal subjects, but the increase was about equal to the gastric pressure increase. Therefore, the LES-gastric pressure gradient remained unchanged. During leg raising, the LES pressure increased more than gastric pressure, thereby increasing the LES-gastric pressure gradient. Although statistically significant, the LES pressure increase (to 32.7 mm Hg) induced by leg raising was modest, unrelated to initial sphincter pressure, and unaffected by atropine. Excluding six individuals demonstrating a "common cavity" phenomenon, LES pressure changes during abdominal compression were similar in patients with esophagitis and controls. Consequently, LES response to abdominal compression does not separate most patients with esophagitis from normal subjects. The observed LES responses to increased intra-abdominal pressure are analyzed in terms of two mechanisms: extrinsic mechanical factors and a physiologic adaptive response of intrinsic LES tone. It is concluded that the findings are best accounted for by extrinsic mechanical factors.

4300 OROPHARYNGEAL DYSPHAGIA: MANOMETRIC AND CINE ESOPHAGRAPHIC FINDINGS. *(E.)* Hurwitz, A. L.; Nelson, J. A.; Haddad, J. K. (Fort Miley VA Hosp., San Francisco, Calif.). *Am. J. Dig. Dis.* 20(4):313-324, 1975.

The manometric and radiographic findings in a group of patients with oropharyngeal dysphagia were systematically studied and correlated. Manometric studies and cine-esophagrams were performed on 14 patients with symptoms of orophayrngeal dysphagia and 15 controls with a variety of other esophageal symptoms, usually related to acid reflux. In the controls, the mean peak pharyngeal pressure was 36 mm Hg; the mean upper-esophageal sphincter (UES) resting pressure was 39 mm Hg; UES relaxation to baseline esophageal pressure was complete in 95% of the swallows; and coordinated UES activity was observed in 98% of the swallows. The oropharyngeal dysphagia patients did not differ significantly from the controls with regard to peak pharyngeal pressures, but the mean UES resting pressure, percent UES relaxation, and percent UES coordination were significantly lower in the former. The cine-esophagrams showed abnormal mouth and tongue movements in seven patients, anatomically disorganized pharyngeal contraction in seven, abnormal UES relaxation in eight, and aspiration in five; initiation of a primary esophageal wave was normal in all but one patient. Peak pharyngeal monometric pressures did not correlate with the cine appearance of pharyngeal contraction; visual observations of the UES did not correlate well with manometric pressures; and the amount and site of aspiration did not correlate with the manometric measurements. However, manometry and cine study agreed in the evaluation of UES relaxation, UES coordination, and evaluation of primary peristalsis. Five patients underwent UES myotomy for severe intractable dysphagia, aspiration, and weight loss; although four patients improved clinically after surgery, the mean and maximum resting UES pressures and peak pharyngeal pressure did not change significantly. The data suggest that both cine-esophagography and manometry are necessary to properly evaluate the abnormalities associated with oropharyngeal dysphagia.

4301 EFFECT OF BILE SALTS ON THE IONIC PERMEABILITY OF THE ESOPHAGEAL MUCOSA AND THEIR ROLE IN THE PRODUCTION OF ESOPHAGITIS. *(E.)* Safie-Shirazi, S.; DenBesten, L.; Zike, W. L. (Univ. Iowa Coll. Med., Iowa City). *Gastroenterology* 68(4):728-733, 1975.

The effects of HCl and HCl plus bile salts on ionic movement across the mucosa of the distally occluded canine and human esophagus were measured to test the hypothesis that HCl, in concentrations secreted by the gastric mucosa, does not significantly penetrate or injure the esophageal mucosa unless its permeability to H+ is altered. Double lumen oroesophageal tubes were placed in the esophaguses of anesthetized mongrel dogs, after which the gastroesophageal junction was occluded and the esophagus was ligated just distal to the thyroid cartilage. A test solution (100 ml) containing 50 mEq/liter HCl with or without 2.5 mM bile salts was instilled into the proximally and distally occluded esophagus, where it was left for 0.5 or 4.5 hr. In two conscious human volunteers, the distal esophagus was occluded and 30 ml of test solution containing 100 mEq/liter HCl with or without 10 mM bile salts was instilled into the esophagus and left for 15 min. In the dogs there was a significant loss of H+ when bile salts were added to the test solution containing HCl. With HCl plus bile salts, but not HCl alone, a severe necrotizing esophagitis with loss of mucosa and submucosa was observed when the solution was left in the esophagus for 4.5 hr. In the human volunteers, the mean net losses of H+ from the esophagus increased five-fold in the presence of bile salts. The data indicate that the addition of bile to HCl significantly increases the loss of H+ and renders the esophageal mucosa more susceptible to inflammatory change. These observations suggest that the esophagitis and ulceration associated with intraesophageal bile and HCl may be due to increased permeability of the esophageal mucosa to H+ induced by bile salts.

STOMACH

4366 GASTRIC CONSEQUENCES OF LONGTERM HYPERCAPNIA IN THE RAT. *(Fr.)* Reichart, E.; Guerrin, F.; Gosselin, B. (Fac. Med., Lille, France). *Biomedicine* 20(5):366-373, 1974.

Continuous hypercapnia without hypoxia was induced in 78 Wistar rats by allowing them to breathe a mixture containing 8 or 10% CO_2 for 1-6 weeks. Some rats were also subjected to a mild hypoxia (17-18%) for 3 days and some had the hypercapnia interrupted for 1 or 7 days before they were sacrificed . Gross and microscopic examinations of the stomachs showed changes in the gastric mucosa in 53/56 rats subjected to hypercapnia for 15 days. Abnormalities included catarrhal or hemorrhagic gastritis, frequent and large areas of desquamation, erosions, and a few ulcerations. Hypercapnia of more than 15 days duration increased desquamation and produced superficial retraction of the mucosa. Hypoxia only mildly aggravated the symptoms, and when the hypercapnia had been discontinued 7 days prior to sacrifice, most lesions had disappeared. It is suggested that local changes in the microcirculation cause most of the gastric lesions, and these results may help clarify gastrointestinal complications which may occur during respiratory insufficiency in man.

4367 HISTOCHEMICAL STUDIES OF ACID PHOSPHATASE IN TUMOR CELLS OF GASTRIC CARCINOMA. *(Rus.)* Dikshtein, E. A.; Vasilenko, I. V. (Donetsk Med. Inst., USSR). *Arkh. Patol.* 36(11):67-72, 1974.

Histochemical studies of the activity of acid phosphatase with β-glycerophosphate at pH 6.0 in 40 gastric tumors (17 adenocarcinomas, six solid cancers, 17 undifferentiated polymorphocellular and mucous cancers) revealed three groups of tumors: with weak (12), moderate (13) and high (15) activity of the enzyme. Phosphatase activity was correlated with the content of fat, total protein, SH-group protein, RNA and amount of mucous secretion in the tumor cells. Undifferentiated tumors appeared to have higher acid phosphatase activity than adenocarcinomas. No direct correlation was found between acid phosphatase and total protein or SH-groups, while a high acid phosphatase activity was accompanied by a low RNA content in the cytoplasm of the tumor cells. It is suggested that acid phosphatase is involved in autolysis, but its involvement in secretion is less obvious; there is an inverse correlation between enzyme and protein synthesis. It is concluded that the activity of acid phosphatase is more indicative of early dystrophic changes in the tumor cells than the amount and distribution of fat.

4368 HISTOLOGICAL AND HISTOCHEMICAL FEATURES OF THE STROMA IN STOMACH CANCER. *(Rus.)* Zolotarevskii, V. B.; Vorobieva, A. A. (1st Moscow Med. Inst. USSR). *Arkh. Patol.* 36(11):61-67, 1974.

Studies were performed on 60 resected stomachs with adenocarcinoma (15), solid cancer (18) and glandular (6), scirrhus (9), undifferentiated (10), and mixed (2) tumors. Three types of stroma were identified. (1) Vascular stroma, found in undifferentiated tumors and adenocarcinomas, consisted of narrow interlayers with small lymph and blood vessels surrounded by a few argyrophilic and collagen fibers and a small number of fibroblasts. No deposits of acid or neutral mucopolysaccharides (MPS) were observed. (2) Granulation tissue-type stroma was identified in all histological types of cancer. It is generally densely infiltrated with leukocytes, plasma cells, histiocytes and lymphoid cells. Acid MPS are either nonexistant or are present in very small amounts. The connective tissue and fibers of the stroma were indicative of immaturity and precollagen and collagen fiber formation. (3) Fibrous stroma was observed in adenocarcinoma and solid and scirrhus tumors. Most collagen fibers stained readily with fuchsin. Fibrous stroma always contained neutral and acid MPS in the interlayers where active synthesis of collagen occurs. The findings suggest a correlation between the presence of fat cells near the tumor and the accumulation of acid MPS in the stroma. Fibroblast proliferation and the increased MPS content in parts of the stomach near the tumor suggest the stroma develops before infiltration of cancer cells.

4369 GASTRIC ULCERATION IN THE PIG SUBJECTED TO HAEMORRHAGIC SHOCK. *(E.)* Kivilaakso, E.; Kalima, T. V.; Lempinen, M. (Second Dep. Surg., Univ. Helsinki, Finland). *Scand. J. Gastroenterol.* 9(7):685-690, 1974.

The mechanism of ulcerogenesis and the roles of transient mucosal ischemia, gastric reflux of bile, and disruption of the mucosal barrier to the backdiffusion of H^+ in the pathogenesis of stress ulcer were studied in 17 piglets. The fasted piglets were subjected to hemorrhagic shock produced by bleeding from a cannulated femoral artery. The gastric motility and the development of the mucosal changes during the shock period and shortly afterwards were followed by endoscopy. Mucosal lesions developed in all but 1 of the 12 piglets which survived the 3 hr of hemorrhagic shock. Endoscopic examination during exsanguination showed inhibition, followed by complete cessation of gastric motilin; this in turn was followed by a copious reflux of bile and the duodenal contents into the stomach. The first mucosal changes, seen soon after the establishment of shock, comprised a network of ischemic and hyperemic areas with extravasation of blood. Toward the end of the shock period, small mucosal hematomas developed within these areas. After transfusion of blood through a femoral vein, these areas became intensely red-colored with transient focal hemorrhages and, later, small superficial erosions were seen. More extensive lesions, confined almost exclusively to the body of the stomach, were seen 24 hr after the cessation of shock; these lesions included 'punched-out' ulcers, superficial ulcerations, and areas of hemorrhagic gastritis. The results indicate that the bleeding shock model is a reproducible and reliable method of inducing stress ulcers in piglets. They also suggest that capillary injury, transient mucosal ischemia, and the gastric reflux of bile and/or the duodenal contents are important factors in the genesis of gastric stress ulcers.

4370 DOUBLE-BLIND STUDY ON THE TREATMENT OF GASTRIC ULCER WITH CARBENOXALONE.

(Fl.) van Camp, F.; Standaert, L. (St. Elisabeth Hosp., Antwerp, Belgium). *Tijdschr. Gastroenterol.* 17(1):51-63, 1974.

A double-blind trial of carbenoxalone was performed on 36 patients with gastric ulcers. Patients with hypertension, cardiac decompensation, and renal damage were excluded, as were four patients who were later found to have stomach cancer, one whose treatment had to be discontinued because of acute appendicitis, and another who stopped taking his medicine. Of the remaining 30 patients, 13 had primary gastric ulcers while 17 were being treated for secondary ulcers or recurrences. This trial was performed on 21 hospitalized patients and six outpatients; three were treated as both inpatients and outpatients. Carbenoxalone was administered to 14 patients in doses larger than those usually recommended: 400 mg/day for the first 2 weeks and 200 mg/day for the next 4 weeks; controls consisted of 16 patients who received placebos. Complete disappearance of the ulcer or a scar with an area of 2 mm^2 at most, as seen on radiological or gastroscopic examination, was observed in eight (66%) of carbenoxalone-treated patients and six (43%) of the controls; improvement occurred in one (8%) and four (29%), resp.; no change was observed in three (25%) and three (21%), resp.; and the condition of one of the controls (7%) became worse. After 3 months of carbenoxalone therapy, 10 (83%) of the carbenoxalone-treated patients were completely recovered. After 6 weeks of therapy, no appreciable difference in weight gain was observed between the two groups, but there was a clearly increased tendency for carbenoxalone-treated patients to retain water and develop edema. It was not clear whether increased ingestion of milk or the presence of sodium bicarbonate in antacids might have contributed to the edema. Reversible increases in blood pressure occurred in two treated patients. Serum sodium concentrations increased in nine (63%) of the treated patients and in six (37%) of the controls, while serum potassium levels decreased in 10 (70%) of the treated patients and in five (36%) of the controls. These changes in serum electrolytes are attributed to water retention which was most pronounced in patients who responded the most rapidly to carbenoxalone. Increases in serum transaminase values, which occurred primarily during week 2 or 3 of treatment, occurred in 12 treated patients and in only two controls; these values later returned to their initial levels.

4371 ENDOSCOPIC FOLLOW-UP OF GASTRIC POLYPS.

(E.) Mizuno, H.; Kobayashi, S.; Kasugai, T. (Aichi Cancer Cent. Hosp., Nagoya, Japan). *Gastrointest. Endosc.* 21(3):112-115, 1975.

The course and malignant changes in a series of 118 patients with gastric polyps (benign) were followed over a period of 1-6.5 yr using endoscopy and histopathological techniques. Of these cases, 114 remained benign and 4 showed malignancy in the final histologic examination. Endoscopic findings in the benign group (61 men and 53 women, average age 54.2 yr) indicated that the rate of morphological change increased with increasing period of observation. The polyps tended to grow over a period of several yr and thereafter remain at about the same size (within 2 cm); in some patients a similar, but reverse, trend was observed. Among the malignant group was a 50-year-old man with a sessile polyp and a pedunculated polyp. The latter increased moderately in size with gradual lobulation; the histological picture suggested an adenocarcinoma engrafted on a polypoid adenoma. In the remaining patients (62- and 64-year-old men and a 63-year-old woman), 2 sessile polyps and a polyp of the lower body of the stomach eventually revealed adenocarcinoma. The results suggest that endoscopic follow-up of benign gastric polyps is justified in that malignant change may occur in a small number of cases.

4372 THE USE OF METOCLOPRAMIDE IN ACUTE PYLORIC OBSTRUCTION: A CLINICAL TRIAL.

(E.) Zer, M.; Dintsman, M. (Beilinson Hosp., Petah Tiqva, Israel). *Am. J. Gastroenterol.* 63(3):232-239, 1975.

Twelve patients (8 men and 4 women, aged 14-68 yr) with complete or partial pyloric obstruction were treated with metoclopramide in an attempt to improve their preoperative state, facilitate radiography, and permit elective surgery. All cases presented with repeated intractable vomiting and would have required urgent surgery. After initial treatment by gastric decompression, i.v. fluids, and electrolyte replacement, 10 mg metoclopramide were administered i.v. or i.m. 3 times daily. Drainage from the gastric tube was measured. After 24 hr an attempt was made to close the gastric tube, withdraw it, and begin p.o. feeding. The drug was continued with a p.o. dose of 30-60 mg/day. If tube removal was unsuccessful, the drug dose was doubled. If this failed to improve the patient's condition, surgery was performed as soon as possible. Of the 12 patients, 8 (66.6%) had very good results; vomiting stopped and p.o. feeding was resumed. Six later had surgery, and diagnosis of duodenal ulcer with severe pyloric stenosis was confirmed. Two cases (16.6%) had good results; vomiting stopped, but severe epigastric discomfort continued, preventing p.o. feeding. In the final two cases, results were poor; the attempts to withdraw the gastric tube failed and semiemergency surgery was performed. Severe scarring and complete pyloric obstruction were found. It is concluded that metoclopramide may effectively improve gastric emptying, sometimes even in complete pyloric obstruction, and allow patients better preparation for surgery.

4373 ROENTGEN PROBLEMS IN EVALUATING THE ATROPHIC STOMACH OF THE ELDERLY.

(E.) Bryk, D.; Elguezabai, A. (Jewish Hosp. Med. Cent. Brooklyn, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):236-241, 1975.

Radiological simulation by gastric atrophy of other conditions was reviewed in 17 patients, 65-89 yr. In eight cases, scirrhous carcinoma of the distal stomach was simulated. Radiograms showed limited distensibility of the stomach with straightening of the lesser and indentations of the greater curvature. Peristalsis was absent or minimal. In two cases there was a scalloped, coarse irregularity of the distal greater curvature. Biopsies in four cases showed absence of malignancy. In six of the 17 cases, gastric retention of food after an overnight fast falsely indicated gastric outlet obstruction. Barium study in these cases showed normal peristalsis with no delay of pyloric opening or gastric emptying. The usual features of gastric atrophy were observed. In three of the cases, there was gastric retention of p.o. cholecystographic medium 14 hr after ingestion. Again, roentgen studies showed features of gastric atrophy, but no delay in pyloric opening or gastric emptying. It is suggested that physicians be aware of such problems in roentgen diagnosis.

4374 EFFECT OF NAPROXEN ON GASTROINTESTINAL MICROBLEEDING FOLLOWING ACETYLSALICYLATE MEDICATION.

(E.) Arsenault, A.; Varady, J.; LeBel, E.; Lussier, A. (Cent. Hosp. Univ., Sherbrooke, Quebec, Canada). *J. Clin. Pharmacol.* 15(4):340-346, 1975.

Naproxen was substituted for acetylsalicylic acid to determine its influence on salicylate-induced gastrointestinal bleeding. Normal volunteers (12) were given increasing doses of salicylate until guaiac tests were positive. Venous blood (16 ml) was drawn, incubated with 200 μCi sodium chromate 51, and the labeled erythrocytes washed and reinjected into the subjects. For the first two weeks of the study, subjects were continued on 2.7-4.5 g/day of acetylsalicylic acid. For the last 2 weeks, the acetylsalicylic acid was stopped; six subjects were given 250 mg naproxen twice daily, and 6 were given a placebo in a double-blind design. Stools were collected on the last three days of each week, and 5 ml of blood was drawn at the beginning and end of each collection period. All samples were counted in a well-type gamma counter. Blood in the stools was quantitated by dividing the net counts/min in the total specimen by the net counts/min/ml blood. The placebo group showed a clear-cut drop in blood loss. A two-way analysis of variance showed a highly significant non-additivity of the Tukey type. On a natural logarithmic scale, the only significant contrast was weeks on acetylsalicylic acid *versus* weeks on placebo therapy. In the naproxen group, there was also a clear-cut difference between weeks on acetylsalicylic acid and weeks on naproxen. Two-way variance analysis showed significant non-additivity. Analysis on a logarithmic scale showed a highly significant contrast between microbleeding during acetylsalicylic acid and naproxen treatment. There was no consistency between acetylsalicylic acid dose and level of microbleeding in either the naproxen or placebo groups. It is concluded that substitution of naproxen for acetylsalicylic acid will significantly reduce microbleeding to near normal levels.

4375 GASTRIC MUCOSAL MORPHOLOGY IN TROPICS AND INFLUENCE OF SPICES, TEA, AND SMOKING.

(E.) Tyagi, K. P.; Mukhopadhyay, A. K.; Agarwal, H. N.; Naik, S. R.; Malik, G. B.; Gupta, D. N.; Chuttani, H. K. (Maulana Azad Med. Coll., New Delhi, India). *Nutr. Metab.* 17(3):129-135, 1974.

Gastric mucosal morphology in the tropics was studied to compare the frequency of gastritis in normal and dyspeptic subjects, and to determine the effects of spices, tea, and tobacco. The dyspeptic group consisted of 82 patients with symptoms suggestive of gastritis, while 6% normal adults served as controls. Peroral gastric biopsies were done in all subjects as well as barium meal examinations. Subjects received either a calculated diet or diet was determined by questionnaire. The amount of spices consumed was calculated by dividing the total amount consumed/family/month by the number of members/family. Spices included *Capsicum frutescens, Elettaria cardamomum, syzigium, armalicum, and Coriandrum sativum.* Tea and cigarette consumption was assessed by questionnaire. Changes of chronic gastritis were significantly higher in the patients (42 of 82) than in the controls (23 of 76). Both superficial and atrophic gastritis were more common in the patients; no subject, patient or control, had gastric atrophy. No radiological evidence of gastroduodenal ulceration was found in either group. Radiological grading of the folds showed 16 of 41 controls and 17 of 31 patients had abnormal folds. No significant differences were noted between moderate and heavy spice consumers in morphological changes of gastritis, or between moderate and heavy tea drinkers. There was no significant difference in occurrence of gastritis between smokers and non-smokers. It is concluded that spices, tea, and smoking are not correlated with occurrence of gastritis.

4376 ROLE OF TAUROCHOLIC ACID IN PRODUCTION OF GASTRIC MUCOSAL DAMAGE AFTER INGESTION OF ASPIRIN.

(E.) Cochran, K. M.; Mackenzie, J. F.; Russell, R. I. (R. Infirm., Glasgow, Scotland). *Br. Med. J.* 1(5951):183-185, 1975.

The possibility that aspirin-induced gastric mucosal damage may occur more readily in the presence of ile was studied in 22 healthy subjects. The subects were fasted overnight and a nasogastric tube ith a probe electrode attached was passed into the ody of the stomach. The gastric transmucosal elecrical potential difference (E.P.D.) was measured fter the stomach had been emptied of any resting ecretion, in the presence of 50 ml of normal saline, nd in the presence of aspirin (600 mg suspended n 50 ml of normal saline) and/or taurocholic acid TCA, 5 mM/liter in normal saline solution). After he introduction of acetylsalicylic acid in 7 subects the mean E.P.D. fell significantly, from a aseline value of -33.3 mV to -17 mV. After the ntroduction of TCA in 7 additional subjects, the ean E.P.D. again fell significantly, from a baseine value of -38.1 mV to -19.1 mV. The mean duraion of the changes following aspirin and TCA adminitration was 14.4 and 17.5 min, resp. When 8 addiional subjects were administered a combination of spirin and TCA, the mean E.P.D. fell from a baseine value of -38.6 mV to -17.9 mV, but the mean uration of this change (27 min) was significantly onger than that after either agent alone. These esults indicate that the ingestion of aspirin, ogether with coincidental reflux of bile from the uodenum, may be a factor in the pathogenesis of spirin-induced gastric mucosal damage.

4377 NARCOTIC ANALGESICS AND DELAYED GASTRIC EMPTYING DURING LABOUR. *(E.)* Nimmo, W. .; Wilson, J.; Prescott, L. F. (R. Infirm., Edinburgh, Scotland). *Lancet* 1(7912):890-893, 1975.

The effects of pethidine, diamorphine (heroin), pentazocine, and metoclopramide on gastric emptying during labor were studied in 56 patients. The women were receiving pethidine (150 mg), diamorphine (10 mg), pentazocine (60 mg), and/or metoclopramide (10 mg) i.m. as needed. Paracetamol (acetaminophen, 1.5 g) was given p.o. at varying times in relation to the narcotic injections and the imminence of delivery. The rate of gastric emptying was measured indirectly based on the kinetics of absorption of the paracetamol. The absorption of paracetamol was also studied 2-5 days postpartum in 10 patients who had received narcotics during delivery. Paracetamol absorption was normal in the postpartum patients and in a control group during delivery. Pethidine and diamorphine significantly reduced the absorption of paracetamol as judged by the plasma-paracetamol concentrations 2 hr after ingestion and the time taken to reach maximum levels. Paracetamol absorption was also markedly delayed in the women taking pentazocine and metoclopramide; the latter drug did not significantly enhance the rate of paracetamol absorption in the patients taking pethidine or diamorphine. There was no relation between delayed paracetamol absorption and the parity of the patients or the administration of cyclizine or oxytocin. The results suggest that the use of pethidine, diamorphine, or pentazocine for the relief of pain in labor may be a major factor responsible for maternal death due to delayed gastric emptying; patients treated with narcotics will also be more likely to vomit or to have increased gastric contents, and they are unlikely to be helped by metoclopramide.

4378 GASTRIC SECRETION IN HYPERPARATHYROID SUBJECTS BEFORE AND AFTER SURGERY. *(E.)* Johansson, H.; Furberg, B.; Krause, U.; Lundqvist, G.; Rimsten, A. (Univ. Hosp., Uppsala, Sweden). *Ups. J. Med. Sci.* 79(3):155-160, 1974.

The effects of parathyroidectomy on the gastric secretion and plasma gastrin levels in patients with hyperparathyroidism were studied. Patients with histologically verified hyperparathyroidism (61) were studied; 41 were preoperatively hypercalcemic, while 20 appeared to be preoperatively normocalcemic. Symptoms of gastritis and/or peptic ulcer disease were present in 11 patients. The gastric secretion rate and hydrogen ion concentration were measured after histamine-stimulation before and 4 weeks after parathyroidectomy. The serum gastrin content was measured by a solid-phase radioimmunoassay. In all patients, the serum calcium level decreased after surgery, the levels being independent of the presence or absence of peptic ulcer disease. Achylia after submaximal histamine stimulation was found in one normocalcemic patient and six hypercalcemic patients, and hypochylia was found in a similar number of patients. The gastric output did not differ significantly before and after surgery in either group, and the preoperative values were of the same magnitude in the two groups. The sialic acid content in the gastric juice also did not change after surgery, but the values were consistently lower in the normocalcemic patients than in the hypercalcemic patients. The serum gastrin level was not influenced by parathyroidectomy. The clinical results suggest that performing parathyroid surgery before surgical treatment of ulcer disease in hyperparathyroid patients with peptic ulcer may be of value.

4379 HEMORRHAGE DUE TO DIFFUSE EROSIVE GASTRITIS. *(E.)* Stremple, J. F.; Elliott, D. W. (Univ. Pittsburgh Sch. Med., Pa.). *Arch Surg* 110 (5):606-612, 1975.

Operative experience (5 yr) with bleeding erosive gastritis is reviewed to help define the safest and most effective surgical approach. Of 796 patients admitted with upper gastrointestinal bleeding during this period, 156 had erosive gastritis. Vigorous nonoperative therapy stopped the bleeding in 117 cases. This treatment program consisted of iced saline lavage, transfusion with packed red blood cells, platelets, or whole blood, vitamin K administration where indicated, antacid administration *via* gastric tube, parenteral anticholinergic therapy, and endoscopic examination. In 39 cases, emergency operations were performed to control hemorrhage. In 24 of these patients (group A), subtotal gastric resection with truncal vagotomy was performed, and in the remaining 15 patients (group B), the operation was limited to pyloroplasty, truncal vagotomy, and multiple suture ligation. The group B patients were, on the average, 20 yr older than the group A patients, and 12 had life-threatening preoperative problems as compared with only four patients in group A. The operative mortality in group A was 42%, with recurrent bleeding occurring in 33%. In group B, only 17% showed recurrent bleeding and the operative mortality was 45%. More than half the deaths in group B were due to sepsis which was present preoperatively. Rebleeding was the cause of death in 33.3% of the group A fatalities and in none of the group B fatalities. The results indicate that truncal vagotomy with pyloroplasty and multiple suture ligation is a good choice of operation in the high-risk and elderly patient in whom the main issue is immediate salvage of life in the face of potential exsanguination.

4380 GASTRIC MUCOSAL CHANGES IN IDIOPATHIC AND POST-HAEMORRHAGIC IRON DEFICIENCY ANAEMIA - A COMPARITIVE STUDY. *(E.)* Gupta, S. P.; Arya, R. K. (Med. Coll., Rohtak, India). *Indian J. Med. Res.* 62(11):1751-1756, 1974.

Gastric morphological and acid-secretory patterns were studied in 20 cases of idiopathic iron deficiency anemia (Group A) and compared with those observed in age- and sex-matched cases of post-hemorrhagic iron deficiency anemia (Group B). The histamine-stimulated acid output was determined and mucosal changes were studied in gastric biopsy specimens. Gastric musocal abnormalities were present in 4/5 of the patients in both groups: atropic gastritis was slightly more common in group A and superficial gastritis was slightly more common in group B. Histamine-fast achlorhydria was present in seven males and two females in group A and six females in group B. The prevalence of gastric abnormalities did not vary significantly with age or sex in either group, although atrophic gastritis was significantly more common in women than in men. The results suggest that the nature of the association between iron deficiency and gastric mucosal lesions is similar in the post-hemorrhagic and idiopathic types of iron deficiency anemia, but that the factors responsible for the negative iron balance are overt in the formen and more subtle in the latter condition. A greater chronicity of iron deficiency may be associated with more severe and permanent gastric changes.

4381 AN ENDOSCOPIC EVALUATION OF THE EFFECTS OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ON THE GASTRIC MUCOSA. *(E.)* Lanza, F.; Royer, G.; Nelson, R. (Baylor Coll. Med., Houston, Tex.). *Gastrointest. Endosc.* 21(3):103-105, 1975.

The effects of placebo (lactose, q.i.d.), phenylbutazone (100 mg, q.i.d.), aspirin (900 mg, q.i.d.). indomethacin (25 mg, q.i.d.), and ibuprofen (a new, nonsteroidal antiinflammatory agent) (300 mg, q.i.d.) on the gastric mucosa were studied in a prospective, single-blind crossover study on 20 normal volunteers. All drugs were given for 7 days. Stool were examined periodically by the guaiac method and the gastric mucosa was evaluated directly before and after drug treatment by endoscopy at the time of gastroscopy. Varying degrees of erythrema, edema, petechial hemorrhage, and gastric erosions were seen with all 4 drugs, the most severe abnormalities being observed with aspirin and indomethacin. The abnormalities caused by ibuprofen were significantly less severe than those induced by aspirin and indomethacin. With aspirin and indomethacin, the degree of mucosal injury was more severe than the subjective symptoms recorded by the subjects; with phenylbutazone, there was almost a direct linear correlation between symptoms and endoscopic findings; and with ibuprofen, there was little mucosal abnormality and minimal subjective symptoms. All drugs were absorbed to a significant extent, and none caused gastrointestinal bleeding, blood chemistry aberrations, or hematologic changes. The findings support previous data indicating minimal gastric mucosal injury with ibuprofen. They also suggest that the cause of sudden painless gastrointestinal bleeding in patients taking antiinflammatory drugs is acute hemorrhagic gastritis.

4382 HEMORRHAGIC EROSIVE GASTRITIS: A CLINICAL STUDY. *(E.)* Lee, E. R.; Dagradi, A. E. (Kaiser-Permanente Bellflower Med. Cent., Calif.). *Am. J. Gastroenterol.* 63(3):201-208, 1975.

The incidence of hemorrhagic erosive gastritis was studied in 400 consecutive patients from a civilian general hospital (over a 7-yr period) presenting with upper gastrointestinal hemorrhage. Age and sex distribution was representative of the general population; race and socio-economic status was a cross section of Southern California. All were examined by endoscopy. Hemorrhagic erosive gastritis was found in 74 of the patients (18.5%), of whom 53 were male and 21 female. This occurred despite a preponderance of female patients (61.8% female versus 38.2% male over a 1-yr period) at the hospital. Of the 74, 55 (74%) had a history of alcohol or salicylate intake. In relating sex distribution to etiologic agent, males were predominant, but no appreciable age difference existed between the sexes in relation to the etiologic agent. Additional peptic lesions were found in 32 patients (43%) and gastric ulcers in 15. In 45 of 54 patients, inflammatory mucosal disease was present, and five had hypertrophic hypersecretory gastropathy. Eleven patients had previously undergone surgery for peptic ulcer. There was a 5% mortality; 2 patients died of hepatic failure, 1 from ruptured esophageal varices, and 1 from fulminant serum hepatitis. This study corroborates findings of a previous all-male VA hospital study. It is concluded that in hemorrhagic erosive gastritis there is a preponderance of males affected, alcohol and/or salicylate is the most common offending agent, and the disease is commonly associated with other gastric mucosal abnormalities.

4383 EARLY GASTRIC CANCER - EXPERIENCE IN GERMANY. *(E.)* Elster, K.; Kolaczek, F.; Shimamoto, K.; Freitag, H. (Munic. Hosp., Bayreuth, Germany). *Endoscopy* 7(1):5-10, 1975.

Cases of early gastric cancer (87) were analyzed and a technique described which allows easy correlation between histological pattern and gross observation. Cases from 1969-1973 were studied; the term early cancer marked not only the spread of invasion but a diagnosis made early in life span. The differentiation between mucosal and submucosal invasion was found to be of special importance in regard to prognostic evaluation of early gastric cancer. Signet ring cell carcinoma was more common in younger age; highly differentiated adenocarcinoma predominated in old age. In 69 of 87 lesions, the first biopsy confirmed the diagnosis of carcinoma. The data suggest that by intensifying gastroscopic biopsy the frequency of diagnosed early cancers will increase.

4384 BENEFICIAL EFFECT OF HUMAN GROWTH HORMONE ON STRESS ULCERS. *(E.)* Winawer, S. J.; Sherlock, P.; Sonenberg, M.; Vanamee, P. (Mem. Sloan-Kettering Cancer Cent., New York, N.Y.). *Arch. Intern. Med.* 135:569-572, 1975.

The potential value of human growth hormone in controlling hemorrhage from stress ulcers was evaluated in 8 patients who had undergone massive upper gastrointestinal tract hemorrhage from verified stress ulcers. Growth hormone was administered i.m. at 10 mg/kg/day for 6 days or until bleeding stopped. Untreated patients with stress ulcer hemorrhage served as controls. Human growth hormone was effective in healing erosions and controlling hemorrhage in 6 of the 8 stress ulcer patients; 2 other patients died during the study, 1 from sepsis and the other from cardiac arrest. Among the patients who responded to treatment, 3 required 4 days of hormone treatment, 2 required 6 days of treatment, and 1 required 18 days of treatment. In the control group, 6 of 8 patients died with continued bleeding. In the patients who responded to hormone treatment, blood urea nitrogen levels were consistently reduced, but the effects on blood sugar, phosphorus, and fibrinogen levels were inconsistent. Although these observations must be extended to additional stress ulcer patients in a larger randomized study, they support data from animal studies and suggest a possible role of human growth hormone in the treatment of human stress ulcers.

4385 PATHOPHYSIOLOGY OF STRESS ULCER AND ITS PREVENTION. I. PHARMACOLOGIC DOSES OF STEROID. *(E.)* Kawarda, Y.; Weiss, R.; Matsumoto, T. (Hahnemann Med. Coll. Hosp., Philadelphia, Pa.). *Am. J. Surg.* 129:249-254, 1975.

The efficacy of large doses of the dexamethasone in the prevention of stress ulcer formation in restrained rats was studied by microangiohistologic techniques. Fasted male Wistar rats were restrained and kept at 4 C for 2 hr. Some of the animals were pretreated (0.1 mg/kg/day for 7 days, or 10 mg/kg 24 hr before restraint) or posttreated (10 mg/kg immediately after restraint) with dexamethasone. Four hr after restraint, the animals were examined for ulcers. In a second study, a double-color perfusion technique was used to study the morphologic changes in the stomach 4 hr after restraint. Compared with the untreated controls, the incidence and severity of ulcers was significantly reduced in the rats pretreated with 10 mg/kg steroid 24 hr before restraint. The other pretreatment group and the posttreatment group did not differ significantly from the controls in terms of ulcer incidence or severity. The microfile perfusion study showed vasoconstriction and focal ischemia in the gastric mucosa of the control group, the posttreatment group, and the group pretreated with 0.1 mg/kg/day steroid for 7 days. Although small areas of ischemia were seen in the group pretreated with a 10 mg/kg dexamethasone, the findings in this group were similar to those in the normal stomach. The results indicate that a large dose of dexamethasone may protect against vasoconstriction, increase inotropic action under conditions of stress, or inhibit damage to gastric cell membranes when given prior to the development of a stress ulcer.

4386 ACUTE GASTRIC MUCOSAL DAMAGE INDUCED BY BILE SALTS, ACID, AND ISCHEMIA. *(E.)* Ritchie, Jr., W. P. (Univ. Virginia Med. Cent., Charlottesville). *Gastroenterology* 68(4):699-707, 1975.

The ulcerogenic potential of topically applied acid and bile salts, alone and in combination with vasopressin-induced mucosal ischemia, was studied. In two groups of healthy adult dogs, vascularized full thickness wedges of a gastric wall were mounted in lucite chambers, and, with mucosa directly visualized, were studied during three consecutive 30-min periods. Group A (five dogs) was subjected sequentially to: topical acid test solution (ATS); ATS plus vasopressin (VP; 0.1 U/kg/min); and ATS plus VP plus 5mM sodium taurocholate (TC). Group B (five dogs) was subjected to ATS, ATS plus TC, and ATS plus VP plus TC. Three groups of controls were also studied: group A^1 were subjected to ATS plus VP during periods 2 and 3; group B^1 was subjected to ATS plus TC during periods 2 and 3; and group C was subjected to topical "neutral" test solution (NTS, 160 mM NaCl), NTS plus TC, and NTS plus VP plus TC. During each period, the net fluxes in volume, H^+, and Na^+, the electrical potential difference, and theaminopyrine clearance, a measure of gastric mucosal blood flow, were determined. Mucosal damage was assessed by an independent observer using photographs obtained after each period. The results indicated that significant lesion formation occurred only in the presence of acid, bile salts, and ischemia, No lesions were noted during any period in the control animals. The data suggest that lesion formation was not a function of either back diffusion of H^+ or of mucosal ischemia, *per se*. Relative to period 1, mucosal blood flow was significantly increased in non-ischemic mucosa exposed to bile salts during vasopressin infusion. Perhaps as a consequence, the combination of mucosal ischemia and topically applied acid and bile salts is severely, acutely, and uniquely ulcerogenic.

4387 ENZYMOLOGICAL CHANGES IN ABNORMAL DIFFERENTIATION: INTESTINAL METAPLASIA IN HUMAN GASTRIC MUCOSA: A POSSIBLE PRECANCEROUS CHANGE. *(E.)* Sugimura, T.; Kawachi, T.; Kogure, K.; Tokunaga, A.; Tanaka, N.; Sasajima, K.; Koyama, Y.; Hirota, T.; Sano, R. (Natl. Cancer Cent. Res. Inst., Tokyo, Japan). *Proc. Third Int. Symposium Princess Takamatsu Cancer Res. Fund, Japan* 251-261, 1973.

The patterns of four intestine-specific enzymes (sucrase, maltase, trehalase, and lactase) in the stomach mucosa were compared with the histological findings in 134 cases of resected stomach. Samples of stomach mucosa obtained at gastrectomy were treated with solutions of 5% sucrose, maltose, or trehalose and incubated to allow formation of glucose from disaccharides. The mucosal surface was then covered with Tes-Tape, which turned the mucosa green in the presence of disaccharides. Negative reactions for sucrase were obtained in 117 cases of stomach carcinoma, but in 96 cases, the cancer areas were surrounded by tissue giving a positive reaction for sucrase. Two patterns of intestinalization were found: In type A, there were positive reactions for sucrase, maltase, trehalase, and alkaline phosphatase with goblet cells and Paneth cells; and in type B, there were positive reactions for maltase and sucrase with goblet cells, but with negative reactions for trehalase and alkaline phosphatase and no paneth cells. Of the specimens examined, 1/3 showed type A intestinalization, 1/3 showed type B, and 1/3 showed both. In the latter cases, type A intestinalization was generally found in the antral region of the stomach and type B was found in the oral region. Intestinalization might be understood in two ways: it may be an obligatory process in cancerization of the stomach mucosa cells; or the stomach epithelium might be converted to a metastable, unidentified state from which both cancer and intestinalization may arise. At present, it is uncertain which of these possibilities is more likely.

4388 PATHOGENESIS OF GASTRIC LESIONS INDUCED BY ASPIRIN IN THE PYLORUS-LIGATED RAT. *(E.)* Okabe, S.; Takeuchi, K.; Nakamura, K.; Takagi, K. (Fac. Pharm. Sci., Univ. Tokyo, Japan). *Jpn. J. Pharmacol.* 24(3):363-371, 1974.

A standard method for the production of aspirin-induced gastric lesions in rats was elaborated and the mechanisms responsible for the deleterious effects of aspirin were investigated. Male Donryu rats were left unoperated or subjected to laparotomy or pylorus ligation. Immediately after surgery, aspirin (100 mg/kg) and/or 1% carboxymethylcellulose (CMC) solution was administered by gastric intubation. The animals were injected i.v. with pontamine sky blue 6 BX 7 hr later, then sacrificed and the stomachs examined for signs of hemorrhage. In other experiments, sodium bicarbonate, L-glutamine, amylopectine sulfate, sulfated glyptide, or atropine sulfate was administered by gastric intubation after surgery and before aspirin treatment. Compared with unoperated rats, laparotomy significantly reduced the incidence of stomach lesions and pylorus ligation significantly enhanced it. The aspirin-induced lesions in the pylorus ligated animals consisted of severe hemorrhagic erosions of various sizes and nonhemorrhagic mucosal defects. Sodium bicarbonate and L-glutamine strongly inhibited the hemorrhagic effects of aspirin; amylopectine sulfate and sulfated glyptide had less pronounced but significant inhibitory effects; and atropine sulfate had no significant inhibitory effects. Aspirin alone significantly reduced the gastric acidity and had no effect on pepsin activity. Sodium bicarbonate, alone or with aspirin, reduced both the acidity and pepsin activity. L-glutamine, alone or with aspirin, reduced the pepsin activity and increased the gastric acidity. Given with aspirin, amylopectine sulfate and sulfated glyptide reduced the pepsin activity and the gastric acidity. Atropine sulfate had no effect on pepsin activity or gastric acidity. These findings suggest that the effect of pylorus ligation on aspirin-induced gastric lesions is due to the increased acidity induced by the former, that L-glutamine may inhibit the aspirin-induced back diffusion of HCl into the gastric mucosa, and that pepsin plays a minor role in the production of aspirin-induced gastric lesions.

4389 CYTOLOGICAL DIAGNOSIS OF CARCINOMA OF THE STOMACH. *(E.)* Sivanagimani, R.; Reddy, D. B.; Raju, G. C. (Med. Coll., Kurnool, India). *Indian J. Cancer* 11(4):433-436, 1974.

The value of cytodiagnosis in gastric cancer was studied using enzymatic gastric lavage in 78 cases of suspected stomach carcinoma. The fasted patients were given several glasses of water the night and morning before the cytological examination. A ryles tube was passed through the mouth into the stomach and the patient was given a glass of water containing 4 mg trypsin. Gastric lavage was performed and the residual liquid was aspirated, centrifuged, and the residue stained. The results showed 16 positive and two suspected cases of malignancy out of 30 proven cases of cancer. Of the positive cases, two specimens showed signet ring shaped cells indicating an adenocarcinomatous pattern. The other specimens showed large irregular clusters of cells exhibiting nuclear and cytoplasmic abnormalities. The smears of the two cases suggestive of malignancy showed cellular atypism. There was no instance of a false positive diagnosis. The percentage of correct diagnoses obtained in this study is rather low in comparison with the findings reported in the literature.

4390 ACUTE GASTRIC DISEASE AFTER CUTANEOUS THERMAL INJURY. *(E.)* Czaja, A. J.; McAlhany, Jr., J. C.; Andes, W. A.; Pruitt, Jr., B. A. (Brooke Army Med. Cent., Fort Sam Houston, Tex.). *Arch. Surg.* 110(5):600-605, 1975.

To determine the clinical and pathologic characteristics of diffuse erosive gastritis following thermal injury, early and serial endoscopic examinations of the stomach and duodenum were performed on 54 thermally injured patients. A total of 79 examinations were performed without complications using a fiberoptic panendoscope. In addition, various blood values were measured on admission and throughout hospitalization, and gastric biopsy specimens were examined histologically. Diffuse erosive gastritis was discovered as early as 5 hr postinjury in 45 of the patients examined. Acute ulcers were identified in 14 patients and concomitant duodenal disease was present in 34. Microvascular fibrin thrombi were not present, even though five patients had disseminated intravascular coagulation. Of seven patients examined before nasogastric intubation, four with a mean burn size of 59.6% of the total body surface had diffuse gastritis. Low total serum protein levels were observed in 81% of the patients tested, but were not predictive of mucosal disease. Hemorrhage followed the clinical deterioration of six patients, and in one patient, an ulcer perforated. It is concluded that whereas coagulation abnormalities, nasogastric intubation, and hypoproteinemia may augment mucosal injury, the morphologic and histologic appearance of the lesions suggested a primary ischemic cause resulting from the opening of submucosal shunts or local vasoconstriction.

4391 INFLUENCE OF L-GLUTAMINE ON ASPIRIN-INDUCED GASTRIC LESIONS AND ABSORPTION AS WELL AS ANTIPYRETIC, ANALGESIC AND ANTI-INFLAMMATORY EFFECTS OF ASPIRIN IN RATS AND MICE. *(E.)* Tanaka, H.; Kiyohara, A.; Orima, H.; Suzuki, Y.; Takagi, K.; Okabe, S. (Pharm. Res. Lab., Kyowa Hakko Kogyo Co., Ltd., Shizuoka, Japan). *Jpn. J. Pharmacol.* 24(6): 903-910, 1974.

The effects of L-glutamine on the absorption and pharmacological actions of aspirin and on aspirin-induced gastric lesions were studied in male Wistar rats and male dd mice. Aspirin (100 mg/kg), aspirin plus L-glutamine (1000 mg/kg), or L-glutamine followed by aspirin were given p.o. to pylorus ligated and nonligated rats, some of which had previously been injected s.c. with yeast suspended in physiological saline. In some cases, a phlogistic agent was administered s.c. following aspirin and/or L-glutamine administration and foot pad swelling was measured. In other experiments, aspirin (300 mg/kg) and/or L-glutamine (1000 mg/kg) was administered to mice, which were later injected i.p. with acetic acid or aconitine. L-glutamine markedly suppressed the development of aspirin-induced gastric lesions in the pylorus-ligated rats. In the nonligated rats, aspirin was absorbed rapidly after administration and was maintained in high concentrations in the blood; L-glutamine administration had little effect on the absorption pattern. In the pylorus-ligated rats, however, aspirin administration was followed by a slow increase in the blood salicylate concentration. L-glutamine administration in these animals increased the blood salicylate level. The combined administration of aspirin and L-glutamine had little effect on the antipyretic, analgesic, or anti-inflammatory effects of aspirin in nonligated normal rats and mice. The results indicate that the effect of L-glutamine on aspirin-induced gastric lesions is not due to an inhibition of aspirin absorption and that aspirin retains its pharmacologic potential in the presence of L-glutamine. Therefore, administration of L-glutamine in combination with aspirin is recommended in clinical situations.

STOMACH

Peptic Ulcers

4482 SERUM PYRIDOXAL IN ACTIVE PEPTIC ULCERATION. *(E.)* Sanderson, C. R.; Davis, R. E. (R. Perth Hosp., Australia). *Gut* 16(3):177-180, 1975.

Fasting serum pyridoxal was assayed by an automated microbiological system in 50 patients (24 men and 26 women, mean age 53 yr) with endoscopically confirmed peptic ulceration. Serum pyridoxal was below normal in 28 of 30 patients with gastric ulceration, one of 14 with duodenal ulceration, one of four with pyloric canal ulceration, and each of two patients with both gastric and duodenal ulceration. Mean serum pyridoxal levels in gastric ulcer and duodenal ulcer patients were 14.7 and 30.8 nM/liter, resp. Although the gastric acid group had a lower mean serum folate level compared with the duodenal ulcer group, no correlation between individual levels was found. The low serum pyridoxal level in patients with gastric ulceration and the normal level in those with duodenal ulceration could not be explained by differences in age, sex, drug use, alcohol intake, or diet. The differences may reflect differing biochemical bases between the two groups, or it may be the result of the ulceration itself.

4483 EFFECT OF METIAMIDE ON THE RESPONSE TO SECRETIN AND CHOLECYSTOKININ IN MAN. *(E.)*

Thjodleifsson, B.; Wormsley, K. G. (Dep. Ther., Univ. Dundee, Scotland). *Gut* 16(1):33-35, 1975.

The effects of i.v. metiamide on the pancreatic exocrine response to i.v. infusion of secretin (1 clinical U/kg/hr) plus cholecystokinin (CCK, 1 Ivy U/kg/hr) was studied in eight patients with duodenal ulceration. Five patients received a continuous infusion of 200 mg/hr metiamide for 1 hr; the remaining three were given a loading dose of 75 mg metiamide prior to continuous infusion of 100 mg/hr metiamide and hormones. The results of the two metiamide schedules did not differ significantly. Metiamide did not alter the secretion of bicarbonate and water. Trypsin secretion in response to secretin plus CCK decreased significantly only during the second 30 min of the 1-hr test. Metiamide virtually abolished gastric acid response to the hormones but had no consistent effect on the cholecystokinetic response. The cause of marked difference between metiamide effects on gastric and pancreatic secretion is not clear. Minimal pancreatic inhibitory effects would be expected if the secretory response to exogenous stimulants depends on interaction between stimulant and receptors and if metiamide acts by competing with gastrin (or hormone) receptors. Alternatively, no inhibitory effect of metiamide on pancreatic secretion would be expected if histamine mediates gastric secretory stimulation by exogenous stimulants but is not involved in mediating the effect of secretin and CCK on the pancreas.

4484 DUODENOGASTRIC REFLUX: A CAUSE OF GASTRIC MUCOSAL HYPERAEMIA AND SYMPTOMS AFTER OPERATIONS FOR PEPTIC ULCERATION. *(E.)*

Keighley, M. R. B.; Asquith, P.; Alexander-Williams, J. (Gen. Hosp., Birmingham, England). *Gut* 16(1):28-32, 1975.

The association between duodenogastric reflux, gastritis, and symptoms was investigated in 30 patients with or without dyspepsia 1-15 yr after gastric ulcer surgery. Patients with biliary disease, hiatus hernia, or recurrent ulceration were excluded from the study. The 30 patients (25 men and five women, mean age 42 yr) were assessed by a symptomatic score, measurement of bilirubin and sodium concentrations in fasting gastric juice, gastric biopsy, and the presence of radiological reflux. In 15 patients with a symptom score of less than median, gastric bilirubin levels were less than 1 mg/ml in 80%; severe endoscopic changes were seen in only one patient and reflux was not observed. Of the 15 patients with a symptom score in excess of the median, 12 had a bilirubin concentration greater than 1 mg/100 ml and four of these had a level in excess of 4 mg/100 ml. Radiological reflux was present in 60% of this group and severe mucosal hyperemia in 50%. There was a significant correlation between symptoms, gastric hyperemia, and duodenal reflux ($P<0.02$). Symptoms closely correlated with duodenal reflux included bile vomiting, nausea, epigastric pain after meals, bile regurgitation, heartburn, and fatty intolerance. Further gastric surgery other than a biliary diversion is likely to aggrevate rather than improve the symptoms.

4485 THE NATURAL HISTORY OF GASTRIC ULCER IN A COMMUNITY: A FOUR-YEAR STUDY. *(E.)*

Mowat, N. A. G.; Needham, C. D.; Brunt, P. W. (Dep. Med., Univ. Aberdeen, Scotland). *Q. J. Med.* 44(173): 45-56, 1975.

All (151) adult patients in northeast Scotland with supposedly benign gastric ulcer first diagnosed in 1967 were studied after a minimum of 4 yr, with a 98% follow-up. The incidence and male:female ratio both increased with advancing age. Ulcers of the body of the stomach were twice as common as ulcers of the antral region. Major coincidental disease (largely cardiovascular, respiratory, or locomotor) was present in 59% of the patients and was the principal cause of 25 of the 29 deaths in the series. Twenty-one patients presented with bleeding but only one other bled subsequently; one patient presented with perforation of gastric ulcer; and two ulcers proved to be malignant. Neither presentation nor course was significantly affected by associated duodenal ulceration (33% of cases). There was a direct correlation between short duration of symptoms and increasing age and mortality. Forty-four (55%) of 82 medically treated patients and 41 (60%) of 69 surgically treated patients were alive and symptom-free at the end of the follow-up period; the respective mortalities were 18.2% and 20.3%. For the whole series, life expectancy was significantly reduced in females (15 deaths *versus* 6.03 expected), but not in males.

4486 CHOLINERGIC STIMULATION OF THE LOWER ESOPHAGEAL SPHINCTER IN PATIENTS WITH VAGOTOMY AND ANTRECTOMY. *(E.)*

Higgs, R. H.; Castell, D. O. (US Nav. Hosp., Philadelphia, Pa.). *Am. J. Dig. Dis.* 20(3):195-200, 1975.

The effect of bethanechol on lower esophageal sphincter (LES) pressure was determined in 10 vagotomized and antrectomized patients (eight men and two women, mean age 45 yr). Both s.c. (0.08 mg/kg) and p.o. (25 mg) administration of bethanechol caused a significant increase in LES pressure in these patients. Sphincter pressure in patients who received the drug s.c. increased from a mean basal level of 16.5 to 41.2 mm Hg at 25 min. Hypotensive basal LES pressure in four patients rose from 8.0 to 41.0 mm Hg. In the six patients given bethanechol p.o., sphincter pressure increased from 11.2 to 19.1 mm

Hg at 75 min. Three of these patients had hypotensive sphincter pressure plus symptomatic gastroesophageal reflux and endoscopic evidence of esophagitis. Following p.o. bethanechol, sphincter pressure rose from 8.0 to 18.3 mm Hg. P.o. administered bethanechol produced a sustained increase in LES pressure throughout a 90-min study period. These studies suggest that cholinergic stimulation of the LES with bethanechol may be of therapeutic benefit in vagotomized and antrectomized patients with gastroesophageal reflux.

4487 DISPERSION ANALYSIS OF PROGNOSTIC AND RELAPSING FACTORS OF DUODENAL ULCER BY USE OF ELECTRON COMPUTER.

(E.) Kawai, K.; Kohli, Y. (Kyoto Prefect. Univ. Med., Japan). *Am. J. Gastroenterol.* 63(1):20-28, 1975.

Complete healing of duodenal ulcers and ulcer scars was documented endoscopically in 109 of 192 patients (92.2% male) studied over a 3-yr period. The 192 cases included 91 with a single duodenal ulcer, 57 with kissing ulcers, and three with multiple ulcers. The shape of single ulcers was round in 49 cases, irregular in 24, long linear in 10, and short linear in eight. After healing, ulcers recurred in 25 cases. Computer analysis of morphologic data showed that linear ulcers were more intractable to healing than round or irregularly shaped ulcers. Increased age was associated with an increased incidence of linear ulcers and a decreased incidence of round ulcers. Ulcers with a marginal swelling appeared to heal more readily than those without it. Number, distribution of lesions, and degree of radiological deformity of the duodenal cap were of no prognostic value. However, kissing ulcers and scars with redness or convergency of mucosal folds showed a tendency to recur. Endoscopy was more useful than radiological examination in description of location, number, shape, and/or stage of duodenal ulcers.

4488 pH DEPENDENCE OF ACID SECRETION AND GASTRIN RELEASE IN NORMAL AND ULCER SUBJECTS.

(E.) Walsh, J. H.; Richardson, C. T.; Fordtran, J. S. (Dep. Med., Univ. California, Los Angeles). *J. Clin. Invest.* 55:462-468, 1975.

Studies were performed on normal subjects and duodenal ulcer patients to assess the effect of gastric acid concentration on the rate of gastric acid secretion and endogenous gastrin release in response to an amino acid or a steak meal. The rate of gastric acid secretion was estimated by measuring the rate of sodium bicarbonate infusion needed to keep intragastric pH constant. Preliminary studies on five normal subjects showed that the secretion rate with an intragastrically instilled amino acid-cornstarch meal was highest at pH 5.5 and was 60% of that produced by a steak meal at the same pH. Progressive lowering of intragastric pH was associated with a stepwise reduction in acid secretion, with secretion at pH 2.5 only half as great as at pH 5.5. The amino acid meal produced increases in serum gastrin that were also less marked than those produced by a steak meal. Increase in serum gastrin over basal concentrations was similar at pH 5.5, 4.0, and 3.0; a measurable increase was not obtained when the meal was maintained at pH 2.5. Six patients with duodenal ulcers (three men and three women, mean age 46.5 yr) were compared with seven normal subjects (three women and four men, mean aged 31.4 yr) at pH 5.5 and 2.5. At both pH values, ulcer patients secreted more acid throughout the 2-hr period following instillation of amino acid meal than did the normal subjects. More important, the degree of inhibition at pH 2.5 was significantly less in ulcer patients. During the second postprandial hr at pH 2.5, acid secretion was suppressed 70% in the controls and only 30% in the patients. These findings suggest a defect in autoregulation of gastrin release and gastric acid secretion at low pH in ulcer patients which may play a role in the pathogenesis of this disease.

4489 ULTRA-STRUCTURAL CHANGES IN THE SMOOTH MUSCULATURE OF ANTRUM AND PYLORUS IN PRESENCE OF ULCUS VENTRICULI.

(E.) van der Zypen, E. (Inst. Anat., Univ. Basel, Switzerland). *Res. Exp. Med. (Berl.)* 164(1):1-17, 1974.

The smooth musculature of the antrum and pylorus of seven patients with one or more stomach ulcers was examined by transmission electron microscopy. The corresponding regions from five normal organ donors served as control material. Electron microscopically visualizable changes were found at distances of up to 180 mm from the site of ulcerous lesions on the smooth muscle cells of the inner and outer longitudinal musculature, and on blood vessels. In the majority of cases, condensation of sarcoplasmic ground substance and myofilaments was observed in combination with distention of hypolemmal vesicles and proliferation of dense bodies. These changes are interpreted as an expression of a pronounced isometric contraction of smooth musculature in the presence of ulcera ventriculi: following glutaraldehyde fixation, the normal stomachs were invariably in a state of relaxation, whereas stomachs with ulceration were partially in a state of isometric contraction. Other changes observed in the presence of stomach ulcer were swelling of the endoplasmic reticulum of smooth muscle cells, lysis of myofilaments, and lacunae. Vacuolization of the endoplasmic cisternae caused displacement of other cell organelles and of the myofilaments. The swelling of the endoplasmic spaces and lysis of the myofilaments indicate degeneration of the muscle cells. The capillary endothelial cells showed degenerative changes that lead to arrest of cytopemtpic processes. In the arteriolar regions, a strong contraction of the smooth musculature frequently resulted in complete occlusion of the vascular lumen. Though further systematic studies are needed, these findings substantiate light microscopy observations on the antral and pyloric musculature in the presence of stomach ulcer.

4490 FAILURE OF SECRETIN RELEASE IN PATIENTS WITH DUODENAL ULCER.

(E.) Bloom, S. R.; Ward, A. S. (Middlesex Hosp., London, England). *Br. Med. J.* 1(5950):126-127, 1975.

Secretin release was studied in 23 patients with duodenal ulcer (21 men and 2 women, mean age 42 yr) and 12 normal subjects (10 men and 2 women, mean age 38 yr). I.v. infusion of pentagastrin (6 μg/kg/hr) produced a plateau of gastric acid secretion that was significantly higher in the duodenal ulcer patients than in the normal subjects. Intraduodenal infusion of 40 ml of 0.1 M HCl resulted in a similar absolute fall in acid output in the two groups, but the rise in plasma secretin levels after intraduodenal acid infusion was significantly higher in controls than in duodenal ulcer patients (52.6 ng/liter *versus* 37.5 ng/liter at 6 min). Patients with symptoms of duodenal ulcer for less than 10 yr and those with a history over 10 yr had a very similar 10-min secretin release (274 and 273 ng/liter/min, resp.). The nine duodenal ulcer patients who smoked 20 or more cigarettes a day had a particularly reduced secretin release compared with that of patients who smoked less than 15 cigarettes a day (216 *versus* 312 ng/liter/min). No correlation was apparent between the amount of secretin released by intraduodenal acid and either the degree of gastric inhibition or the level of the initial gastric acid plateau. These results demonstrate that patients with a duodenal ulcer have an impaired secretin release in spite of requiring greater pancreatic bicarbonate output to neutralize a larger gastric acid load.

4491 THE EFFECT OF AN H_2-RECEPTOR ANTAGONIST ON FOOD-STIMULATED ACID SECRETION, SERUM GASTRIN, AND GASTRIC EMPTYING IN PATIENTS WITH DUODENAL ULCERS: COMPARISON WITH AN ANTICHOLINERGIC DRUG. *(E.)* Richardson, C. T.; Bailey, B. A.; Walsh, J. H.; Fordtran, J. S. (Univ. Texas Health Sci. Cent., Dallas). *J. Clin. Invest.* 55:536-542, 1975.

The effects of isopropamide (an anticholinergic drug) and metiamide (an H_2-receptor antagonist) on food-stimulated acid secretion were compared. Seven duodenal ulcer patients (two women and five men, mean age 41.7 yr) were stimulated by a steak meal, and acid secretion was measured by *in vivo* intragastric titration. A maximum tolerated p.o. dose of isopropamide (20-40 mg/dose) inhibited food-stimulated acid secretion by a maximum of 35%. In contrast, a 400-mg dose of p.o. metiamide produced no side effects and inhibited secretion by 96%. A maximum tolerated dose of isopropamide and 300 mg metiamide suppressed food-stimulated acid secretion to a greater extent than 400 mg metiamide alone (88 mEq reduction *versus* 63 mEq). Neither isopropamide nor metiamide affected serum gastrin concentration or gastric emptying. If given before meals, metiamide was most effective during the early posprandial period, whereas if given after meals, it was most effective during the second hr after eating. The duration of action was at least 3 hr. These results indicate that histamine has a dominant role in mediating food-stimulated acid secretion and that the specific inhibitory effect of metiamide on acid secretion is not mediated through inhibition of gastrin release.

4492 THE EFFECT OF HISTAMINE ON GASTRIC SECRETION IN PATIENTS WITH PEPTIC ULCER. *(Rus.)* Voinova, M. Kh.; Kliminskii, I. V. (2nd Moscow Med Inst., USSR). *Khirurgiia (Mosk.)* (4):58-62, 1974.

Studies were carried out on gastric acid secretion and the histamine content of the gastric juice, blood and tissues of 24 males with peptic ulcer (18 had ulcers in the duodenum, 6 in the stomach). Six healthy adults served as the controls. Tests were made to determine the basal acid output (BAO) and maximal acid output (MAO) after stimulation with exogenous histamine (0.04 μg/kg). In patients with duodenal ulcer, the histamine content in the blood did not differ significantly from that of the controls, while excessive acid secretion was observed in the stomach: BAO 6.25±0.81 mEq/hr and MAO 37.22±0.64 mEq/hr (in healthy adults: 2.1±0.64 and 10.5±3.0 mEq/hr, resp.). Basal histamine secretion with the gastric juice averaged 132.8±27.8 μg/hr and in stimulated secretion, 160.23±6.4 μg/hr. Drug-induced (benzohexonium and atropine) and surgical vagotomy significantly decreased histamine secretion and the histamine content in the gastric juice. A correlation was found between acid and histamine content in the gastric juice in patients with stomach ulcer. It is suggested that histamine content in the gastric juice in patients with duodenal ulcer is closely related to the tonus of the vagus nerve.

4493 CERTAIN PROBLEMS OF HEREDITY ASSOCIATED WITH PEPTIC ULCER. *(Rus.)* Frolkis, A. V.; Somova, E. P. (Petrozavodsk University, USSR). *Klin. Med. (Mosk.)* 52(8):120-124, 1974.

Family studies of 124 peptic ulcer patients showed that in 35 (28.2%) families relatives of the propositi had a prior history of the disease. Adverse family histories (peptic ulcer, gastritis, epigastric pain, intestinal cancer) among the patients' families was 5.5 times greater than among the families of 124 controls with no gastrointestinal disease (52.4% and 9.6%, resp.). There were significantly more peptic ulcer patients with the O(I) blood group and among the nonsecretors of A, B and AB antigens. Starch gel electrophoretic studies of serum alkaline phosphatase isoenzymes from peptic ulcer patients showed that the slow-moving B component was absent in 58% of the patients, mostly those with the A(II) blood group. Serum pseudocholinesterase in peptic ulcer patients was significantly lower than in healthy controls (0.46±0.016 and 0.58±0.021 U, resp.). Further electrophoretic studies showed that fraction 3 of cholinesterase was missing in 35.5% of the patients, mostly those with the A(II) blood group. These findings confirm that there are 2 types of peptic ulcer: one related to the genetic factors (patients with the O(I) blood group, nonsecretors with certain types of alkaline phosphatase and pseudocholinesterase and another associated with phenotype.

4494 PERSISTENT INHIBITION OF GASTRIC SECRETION BY AN INTRAVENOUS 12-HOUR INFUSION OF CALCITONIN IN NORMALS, PEPTIC ULCER AND HIGH RISK PATIENTS. *(E.)* Hotz, J.; Goebell, H.; Minne, H.;

Ziegler, R. (Cent. Intern. Med. Pediatr., Univ. Ulm, Germany). *Digestion* 11(3/4):311-314, 1974.

The effect of a 12-hr infusion of thyrocalcitonin (20-60 MRC U/hr) on unstimulated acid and pepsin secretion was studied in 4 healthy volunteers, 3 peptic ulcer patients and 3 high risk patients. The high-risk patients suffered from cerebral ischemic syndrome, pulmonary decompensation, and subarachnodial hemorrhage, resp. A striking reduction of total acid output took place in 3 normal subjects and in 2 peptic ulcer patients compared with control experiments. All high-risk patients showed a marked suppression of acidity during and after thyrocalcitonin infusion (40 MRC U/hr). Pepsin secretion paralleled acid output in all cases. In 4/7 cases, side effects (slight nausea and transient headache) occurred. The results suggest that the therapeutic application of thyrocalcitonin by an i.v. route may be restricted to selected cases.

4495 RESULTS OF STIMULATION OF THE STOMACH WITH HISTALOG IN 32 NEGROES WITH CHRONIC DUODENAL ULCER.

(E.) Lutete-Kelani, M. (Clin. Intern. Dis., Natl. Univ. Lubumbashi, Zire). *Mater. Med. Pol.* 6(2):136-139, 1974.

Gastric secretion after betazole was studied in Africans suffering from duodenal ulcer, and the values were compared with normal values from Europeans. Basal and betazole-stimulated (2 mg/kg, s.c.) gastric secretion was collected in 15-min portions during 90 min from 32 patients (26 men and 6 women) with chronic duodenal ulcer. Basal gastric secretion (2.45 ± 2.3 mEg/liter in men and 0.69 in women) did not exceed the normal values for Europeans. Gastric secretion stimulated with betazole in the same group of patients (17 ± 10.91 mEg/liter in men and 8.6 in women) was within normal values. The data suggest that hypersecretion of gastric juice is not an essential factor in the pathogenesis of duodenal ulcer in black Africans.

4496 EFFECTS OF AN ANTIULCER AGENT, N-ACETYL-L-GLUTAMINE ALUMINUM COMPLEX (KW-110) ON THE DUODENAL AND GASTRIC ULCER MODELS IN THE RAT.

(E.) Takagi, K.; Takeuchi, K.; Nakamura, K.; Morita, A.; Okabe, S. (Fac. Pharm. Sci., Univ. Tokyo, Japan). *Jpn. J. Pharmacol.* 24(3):357-361, 1974.

The effects of N-acetyl-L-glutamine aluminum complex (KW-110) and atropine sulfate on duodenal and gastric ulcers were compared in studies on male Donryu rats. KW-110 (p.o. for 8 days) significantly accelerated the healing of duodenal ulcers at 1000 mg/kg/day (38.0%) or 3000 mg/kg/day (40.0%). The effect of atropine sulfate (20 mg/kg/day for 8 days, s.c.) was not significant. Although atropine sulfate (10 mg/kg) completely inhibited stress ulcer formation, KW-110 was also strongly inhibitory at 500 mg/kg (66.0%) or 1000 mg/kg (81.7%). At 500 and 1000 mg/kg, KW-110 inhibited Shay ulceration by 44.3% and 100%, resp., and aspirin-induced lesions by 32.8% and 69.1%, resp. At 10 mg/kg, atropine sulfate inhibited Shay ulceration and aspirin-induced lesions by 74.4% and 33.8%, resp. Prevention of Shay ulceration by KW-110 appeared to be caused by raised pH value and reduced pepsin activity. These results confirm that KW-110 is a promising antiulcer agent in experimental gastrointestinal ulcer models.

4497 CONTROLLED STUDY OF THE SURGICAL TREATMENT OF DUODENAL ULCER.

(E.) Dwight, R. W.; Schimmel, E. M.; O'Hara, E. T.; Hechtman, H. B.; Williams, L. F.; Vollman, R. W.; Maselli, J. P.; Johnson, W. C.; Nabseth, D. C. (Boston VA Hosp., Mass.). *Am. J. Surg.* 129(4):374-379, 1975.

Vagotomy and drainage was compared with vagotomy and hemigastrectomy in treatment of duodenal ulcer. Of 100 male veterans, 51 were selected for hemigastrectomies and 49 for drainage procedures on a random basis. Of the hemigastrectomies, 18 were Billroth I and 33 Billroth II operations; of the drainage procedures 28 were Heinke-Mikulicz, 5 Jaboulay, 8 Finney, 2 Wagensteen pyloroplasties, and 6 posterior gastroenterostomies. Both patient groups were comparable in age, duration of symptoms, and preoperative peak acid output. Every 3 months in the 1st yr after surgery, and then every 6 months, each patient was weighed and given a questionnaire about work, bowel and eating habits, symptoms, and use of medication. The abdomen was examined for tenderness, succussion, solidity of the scar; blood was tested for serum iron, iron-binding capacity, and hematocrit; and stools were given a guaiac test. Surgical results were considered excellent when patient had no complaints; good when there were mild symptoms; and poor when symptoms were marked enough to affect the patient's way of life; and a failure when ulcer recurred, reoperation was necessary, or incapacitating dumping and malnutrition occurred. Follow-up was 5 yr or more in 52 patients, 3 yr in 80, and at least 1 yr in the remainder, excluding 3 who were not followed up. Operating time was significantly longer for hemigastrectomy (245 min) than for drainage (170 min) and transfusion was required in 15 of the former and 4 of the latter. Six major complications and five minor ones occurred after resection, while 2 major and 8 minor complications occurred after drainage. After resection, results were excellent in 45%, good in 35%, poor in 9% and failure in 8%. After drainage, the corresponding results were 58%, 25%, 8%, and 8%, resp. Failures after resection included 2 recurrent ulcers, 1 reoperation for stomal obstruction, and 1 case of severe dumping and malnutrition. Failures after drainage included 3 recurrent ulcers, 1 reoperation for pyloric obstruction. The type of drainage procedure or anastomosis used did not affect the results. Blood tests showed no significant differences between the two groups. Mean weight loss was significantly greater after resection (17.5 pounds) than drainage (10.5 pounds). It is concluded that there is no significant difference on mortality or recurrence of ulcers between vagotomy and resection and vagotomy and drainage; however, as nutrition is maintained better after drainage, this procedure is recommended.

4498 GASTRO-DUODENAL ULCER IN KIDNEY-TRANSPLANTED PATIENTS RECEIVING IMMUNOSUPPRESSIVE TREATMENT. *(E.)* Rasmussen, K.; Christiansen, J.; Nielsen, O. V.; McNair, A.; Sorenson, M. B. (Glostrup Hosp., Denmark). *Acta Chir. Scan.* 141(1):61-64, 1975.

The clinical course was evaluated in 14 cases of gastroduodenal ulcer in kidney-transplanted patients receiving immunosuppressive therapy. Of 229 patients who received kidney transplants in the Copenhagen hospitals between 1968 and 1973, 14 had or developed peptic ulcers requiring treatment in connection with the transplantation. In three patients a prophylactic gastric operation was carried out prior to the kidney transplantation; in two with ulcer dyspepsia during the uremic period, conservative treatment with antacids and controlled diet was given prior to transplantation; conservative treatment was also given in three cases of peptic ulcer complications during immunosuppressive treatment; and surgery was performed in five patients with peptic ulcer complications during immunosuppressive treatment. Among the eight patients in whom bleeding peptic ulcer occurred during immunosuppressive therapy, six died due to hemmorrhage. Five were operated acutely, three of whom died. In three in whom the ulcer was neither removed nor excluded, hemmorrhage from the same ulcer recurred during immunosuppressive treatment. Of the patients treated with prophylactic surgery prior to kidney transplantation, only one showed symptons of transient dyspepsia during immunosuppressive therapy. The results indicate that a verified peptic ulcer occurring prior to transplantation should be subjected to prophylactic surgery. In the case of ulcer dyspepsia arising during immunosuppressive treatment, the treatment should be elective surgery and discontinuation of the immunosuppressive drugs during the healing period. Radiological examination of the stomach and esophagogastroduodenoscopy should be a standard procedure prior to kidney transplantation.

4499 EFFECT OF ATROPINE ON GASTRIC SECRETION OF ACID, PEPSIN, AND ELECTROLYTES ELICITED BY MAXIMAL STIMULATION WITH HISTAMINE AND PENTAGASTRIN IN NORMAL CONTROL AND DUODENAL ULCER PATIENTS FROM BOMBAY. *(E.)* Pimparkar, B. D.; Bhiwankar, N. T.; Kulharni, B. S.; Mehta, J. M. (K. E. M. Hosp., Bombay, India). *Indian J. Med. Res.* 62(11):1736-1750, 1974.

To determine whether gastric acid secretion stimulated by augmented doses of histamine and pentagastrin could be suppressed by atropine, an augmented histamine test (76 μg/kg histamine acid phosphate) and a pentagastrin test (6 μg/kg) were carried out in 10 normal controls and 15 patients with duodenal ulcer. Atropine (1.2 mg) was given twice, once during the basal period and again after stimulation with histamine and pentagastrin. In both controls and patients, atropine significantly suppressed basal and stimulated acid secretion. During the basal period and after stimulation with histamine or pentagastrin, atropine resulted in identical suppression in gastric pepsin, sodium, potassium, and chloride in both groups. With atropine there was significant suppression in volume but no significant changes in the concentration of acid pepsin and electrolytes. It is concluded that histamine and pentagastrin act through the vagus since their action after augmented doses is suppressed by atropine. The predominant action of atropine is a decrease in gastric secretory volume which reflexly limits the output of various ingredients, even though there is no significant change in their concentrations.

4500 STUDIES ON THE HEALING OF EXPERIMENTAL ULCER IN THE RAT II: INFLUENCE OF ANTI-INFLAMMATORY DRUGS ON THE HEALING OF THE ACETIC ACID ULCER AND THE COMPONENTS IN GASTRIC TISSUE. *(E.)* Takagi, K.; Abe, Y. (Fac. Pharm. Sci., Univ. Tokyo, Japan). *Jpn. J. Pharmacol.* 24(3):345-356, 1974.

The relation between chemical components of an acetic acid ulcer site and ulcer healing was investigated in male Donryu rats together with the effects of antiinflammatory drugs on the ulcer. The hexosamine content in the corpus of normal rat stomach decreased when sodium salicylate (0.5%) or phenylbutazone (0.2%) was added to the diet for 20 days. Both sodium salicylate and phenylbutazone delayed the healing of 10% acetic acid ulcer, and resulted in a simultaneous decrease in hexosamine at the ulcer site. Prednisolone (25 mg/kg s.c.) and cortisone (50 mg/kg s.c.) retarded ulcer healing in the early stages of administration, when hexosamine and hydroxyproline decreased significantly. Sodium salicylate, by contrast, delayed ulcer healing in the early and also later stages of administration. A decrease in hexosamine content in the injured mucosa and a decrease in hydroxyproline content in the injured stroma paralleled an increase of area index and grade index, resp. These results suggest that the mucosal hexosamine and stromal hydroxyproline content in the injured portion play an important role in ulcer healing. The data also demonstrate differences between steroidal and nonsteroidal anti-inflammatory agents with respect to retardation of ulcer healing.

4501 CYSTEAMINE-INDUCED DUODENAL ULCERS: A NEW MODEL TO TEST ANTIULCER AGENTS. *(E.)* Robert, A.; Nezamis, J. E.; Lancaster, C.; Badalamenti, J. N. (Upjohn Co., Kalamazoo, Mich.). *Digestion* 11(3/4):199-214, 1974.

The effect of various agents on cysteamine-induced ulcers and the effect of cysteamine on gastric secretion were studied in Upjohn rats to evaluate the procedure as an assay for antiulcer agents. Cysteamine was administered at doses 230-465 mg/kg, s.c. and 460-900 mg/kg, p.o.; the duodeno-ulcerogenic property of cysteamine was dose-dependent after either route of administration. Duodenal ulcers were produced within 24 hr; at least 50% of the ulcers perforated with 425 mg/kg, s.c. Cysteamine-induced duodenal ulcers were prevented by an anticholinergic agent (methscopolamine bromide), by an antacid (Malcogel) by prostaglandins (PGE_2 and 16,16-dimethyl PGE_2), by prednisolone, and by interruption of the gastroduodenal transit (pylorus ligation). Fasting did not affect the incidence but reduced the severity of the ulcers. Incidence and severity were higher in female than in male rats. Deoxycorticosterone and ACTH did not affect the ulcers. Gastric secretion was inhibited by cysteamine and was dose-dependent; however, some acid secretion and the passage of acid gastric contents over the duodenum were required for cysteamine to produce ulcers. The results indicate that cysteamine-induced duodenal ulcers provide an excellent model for the study of antiulcer agents.

4502 EFFECT OF METIAMIDE ON HISTAMINE METABOLISM IN MAN. *(E.)* Shepherd, D. M.; Thjodleifsson, B.; Turnbull, M. J.; Wormsley, K. G. (Dep. Pharmacol. Ther., Univ. Dundee, Scotland). *Digestion* 11(3/4):307-310, 1974.

The effect of metiamide on the urinary excretion of histamine, 1,4-methylhistamine, and 5-hydroxyindol-3-yl-acetic acid was studied in 12 duodenal ulcer patients (aged 22-65 yr) receiving metiamide therapy (600-1200 mg/day). Administration of metiamide resulted in an increased excretion of 1,4-methylhistamine (263 to 465 µg/24 hr) and a decreased secretion of histamine (29.5 to 19 µg/24 hr). The excretion of 5-hydroxyindol-3-yl-acetic acid was not significantly affected. Blood metiamide levels were 1 to 6 x 10^{-6}M and the urinary amine excretion pattern was compatible with an *in vivo* stimulation of histamine methyltransferase (HMT) activity. If histamine is involved in mediating the gastric secretory response to stimulants in man, then the stimulation of HTM activity by metiamide may contribute to the inhibition of gastric secretion produced by the drug.

4503 GLYCOPROTEINS IN THE STOMACH OF PATIENTS WITH GASTRIC AND DUODENAL ULCERS: PATHOPHYSIOLOGICAL FINDINGS AND EFFECT OF TREATMENT. *(Cz.)* Domschke, W.; Demling, L. (Clin. Intern. Med., Univ. Erlangen-Nuremberg, Erlangen, Germany). *Vnitr. Lek.* 20(7):625-630, 1974.

The rate of gastric acid secretion was measured before and for 1.5 hr after pentagastrin infusion (1.5 g/kg/hr i.v.), as was the output of glycoproteins containing *N*-acetylneuraminic acid (NANA), in 22 patients with gastric ulcers, 20 with duodenal ulcers, and in 45 normal controls. These studies were performed on patients before and 4 weeks after carbenoxalone treatment. Patients with gastric ulcers were given 300 mg/day carbenoxalone sodium for 1 week and then 150 mg/day, while patients with duodenal ulcers received 300 mg/day of the enteric-coated form of the drug. In normal subjects there was a very good linear relation between the peak acid output and the production of glycoproteins containing NANA. This relation was also evident in patients with gastric ulcers, but the rate of HCl production was greater than in controls. No such relation was found between these two parameters in patients with duodenal ulcers. After 4 weeks of treatment with carbenoxalone sodium, the output of glycoproteins containing NANA increased significantly and even exceeded normal values in patients with gastric ulcers. However, carbenoxalone sodium did not stimulate mucus production in the stomach of patients with duodenal ulcers since the drug was not absorbed until after it had passed through the stomach.

4504 CALCULATED MAXIMAL RESPONSE AND ED_{50} FOR ACID SECRETION IN CONTROL SUBJECTS AND PATIENTS WITH DUODENAL ULCER. *(E.)* Desai, H. G.; Zaveri, M. P.; Antia, F. P. (B. Y. L. Nair Charitable Hosp., Bombay, India). *Indian J. Med. Res.* 62(12):1843-1849, 1974.

Values of calculated maximal response (CMR) and ED_{50} on i.v. histamine tests were determined in 13 control subjects in India and 20 male patients with duodenal ulcer. Dose-response curves were obtained using 0.4-2.8 mg/kg doses of histamine acid phosphate. The mean ED_{50} value was lower in ulcer patients (9.7 ± 5.3 µg/kg/hr) than in controls (12.5 ± 5.3), but the difference was not significant. CMR values in controls (8.0 ± 2.3 mEq/155 min) and in patients (10.1 ± 3.1) were significantly different, as were the highest observed values (HOV) of acid output (6.3 ± 1.5 mEq/15 min in controls and 8.5 ± 2.7 in patients). However, the lowest HOV value (2.5 mEq/15 min and the lowest CMR value (3.5 mEq/15 min) were observed in duodenal ulcer patients. The value of ED_{50} in relation to body weight showed a significant correlation with the body weight of controls but not of ulcer patients. The ED_{50} vlaues obtained in this study differ from those reported for North American patients with duodenal ulcer; the difference may result from marked differences in maximal acid output in the patients from these countries.

4505 SECRETION OF GASTRIC LIPASE, PEPSIN AND HYDROGEN IONS FOLLOWING PENTAGASTRIN ADMINISTRATION IN PATIENTS WITH DUODENAL ULCER. *(Pol.)* Trompeter, G.; Komarowska, M.; Szafran, Z.; Popiela, T. (Med. Acad., Krakow, Poland). *Przegl. Lek.* 31(2): 287-293, 1974.

Pentagastrin was administered for 3 hr by continuous i.v. infusion to six male patients (aged 20-43 yr) with duodenal ulcer. The dose was increased every 30 min (8, 64, 256, 1024, 2048, and 8192 ng/kg), gastric juice collected every 10 min and hydrogen ion concentration as well as lipase and pepsin activity determined in each of the 18 fractions. In fasting gastric juice the hydrogen ion concentration varied between 10-61 mEq/liter, activity of lipase between 0.67-4.61 U/min/ml, of pepsin 0.18-0.56 x 10^{-2} Anson U/min/ml. Highest lipase activity was obtained in fraction collected after 140-150 min, the highest pepsin activity 70-80 min, highest ion concentration 130-140 min of test. Despite a great variation in values, statistical analysis revealed a highly significant positive correlation between all three measured parameters. The most significant correlation coefficient was obtained between hydrogen ion concentration and lipase activity. In calculations taking into account the output values a high correlation coefficient was obtained for output of both enzymes. It is concluded that pentagastrin stimulation caused active secretion not only of pepsin and hydrogen ions but also of gastric lipase.

4506 STUDIES ON THE BIOELECTRICAL ACTIVITY OF THE STOMACH IN PEPTIC ULCER. *(Pol.)* Wryzykowski, R.; Szczgiel, B.; Rucinski, J. (Med. Acad., Warsaw, Poland). *Przegl. Lek.* 31(2):283-286, 1974.

External electrography using the EMA electrogastrograph Model EGS-4M was performed on 21 healthy volunteers, 10 patients with gastric, 14 with duodenal ulcer and six with narrowing of the pylorus. The tests were performed after overnight fasting and in the control group also after food, atropine or prostygmine stimulation. The time of recordings varied between 10-60 min. The electrogastrograms were interpreted by calculating the average frequency of biopotential changes/min and average amplitude in mV. It was found that in comparison to controls (average frequency/min = 3.5, average ampliture/mV = 0.3) the basal electrical rhythm was decreased in patients with gastric ulcer in regard to average frequency (1.1) and average amplitude (0.1); increased in regard to average frequency (4.5) without change in amplitude in patients with duodenal ulcer, while in patients with narrowing of the pylorus and ulcer a significant increase in amplitude (0.8) without change in frequency was observed. Both frequency and amplitude increased. Atropine (0.5 mg) caused a decrease in amplitude and slowing down of frequency. Prostigmin caused a significant increase in the bioelectric activity of the stomach both in regard to amplitude and frequency.

4507 EFFECT OF CALCIUM AND HISTAMINE ON GASTRIC ACID SECRETION IN MAN. *(E.)* Dalal, N. J.; Vakil, B. J.; Gangrade, R. R.; Bhise, K. B.; Shah, P. N. (J. J. Group Hosp., Bombay, India). *Indian J. Med. Res.* 62(11):1652-1658, 1974.

Gastric acid secretion in response to calcium infusion and subsequent histamine injection was studied in seven Indian patients with duodenal ulcer, six patients with hyperacidity, and seven normal subjects. Calcium infusion (4 mg/kg/hr, i.v., for 3 hr) resulted in a significant rise in gastric acid secretion over basal values; the calcium-stimulated maximum acid output was 2.19 times the basal output in controls, 2.23 times the basal output in duodenal ulcer cases, and 2.84 times the basal output in hyperacidity cases. Histamine administration (0.04 mg/kg s.c.) induced a further rise in acid secretion. Maximum acid secretion after calcium infusion was 63% and 55%, resp., of post-histamine values in patients with duodenal ulcer and those with hyperacidity; in controls the post-calcium value was 41% of the post-histamine value. The difference in the response between controls and the duodenal ulcer and hyperacidity cases was significant, whereas the difference in the response between the two groups of patients was not significant. To determine if there is any potentiation between calcium and histamine, four controls were infused with histamine (0.04 mg/kg/hr) until a steady state of gastric acid secretion was reached; calcium was then given simultaneously with histamine for 2 1/2 hr. No further increase in gastric acid secretion occurred in response to the calcium infusion. The absence of potentiation between histamine and calcium indicates that calcium provides a submaximal stimulus for acid secretion compared with histamine.

4508 HIGHLY SELECTIVE VAGOTOMY FOR DUODENAL ULCER: DO HYPERSECRETORS NEED ANTRECTOMY? *(E.)* Johnston, D.; Pickford, I. R.; Walker, B. E.; Goligher, J. C. (Gen. Infirm., Leeds, England). *Br. Med. J.* 1(5960):716-718, 1975.

Patients who had undergone highly selective vagotomy for duodenal ulcer were reviewed 2-6 yr later to determine if the surgical treatment was adequate or if antrectomy was also needed in hypersecretors. The clinical results in 40 hypersecretors were compared with those in 60 patients with normal acid secretion. The overall clinical results were similar in both groups; the incidence of pain of ulcer type was 6% in each group, peak acid output was similar in both groups, and the incidence of incomplete vagotomy was 7% in each group. In no case was a recurrent ulcer seen. The incidence of individual symptoms was about equal in the two groups, however early dumping was recorded in 1% of hypersecretors compared with 6% of normal secretors. The results suggest that the addition of antrectomy to vagotomy is unnecessary when patients with hypersecretion are treated by highly selective vagotomy, providing the vagotomy is complete.

4509 MARGINAL ULCER IN ACHLORHYDRIC PATIENTS. *(E.)* Tauxe, R. V.; Wright, L. F.; Hirschowitz, B. I. (Dep. Med., Univ. Alabama, Birmingham). *Ann. Surg.* 181(4):455-457, 1975.

Details of three cases of endoscopically proven anastomotic ulceration were reported in patients with histamine-fast achlorhydria. Basal secretion was collected in 15-min samples for 1 hr; volume and pH determinations were made. Histamine acid phosphate (0.04 mg/kg) was injected s.c. after basal secretion collection and 20 mg benadryl was also injected to minimize side effects. Two cases demonstrated anemia and two had pernicious anemia. Achlorhydria was present even in the two who had not undergone vagotomy. All three patients had a history of alcohol abuse, and one abused aspirin as well. The cases demonstrated that achlorhydria did not protect against anastomotic ulceration and that it may be erroneous to consider all anastomotic ulceration as a continuation of the original peptic disease. The results suggest that stomal ulceration is frequently a multifactorial disease which occurs because the gastrojejunal stoma has less resistance to damage than does the adjacent unaltered gastric and jejunal mucosa.

4510 A CONTROLLED, RANDOMIZED TRIAL OF HIGHLY SELECTIVE VAGOTOMY VERSUS SELECTIVE VAGOTOMY AND PYLOROPLASTY IN THE TREATMENT OF DUODENAL ULCER. *(E.)* Kronborg, O.; Madsen, P. (Bispebjerg Hosp., Copenhagen, Denmark). *Gut* 16(4):268-271, 1975.

The results of highly selective vagotomy without drainage and selective vagotomy with pyloroplasty for duodenal ulcer were compared in a randomized, controlled trial of a series of 100 patients. Fifty patients received one method of treatment and 50 the other. The clinical results were obtained 1 yr after operation. The frequency of dumping, diarrhea, and epigastric fullness was significantly lower after highly selective (6, 6, and 8%) than after selective vagotomy (30, 20, and 28%). Recurrent and persisting duodenal ulcers appearing 1-4 yr after operations were significantly more frequent after highly selective (22%) than after selective vagotomy (8%). No significant relations were found between recurrent ulceration and gastric acid secretion measurements after the two operations. The Hollander response was early positive in 28% and late positive in 30% of the patients subjected to highly selective vagotomy, while the corresponding figures after selective vagotomy were 26 and 32%, resp. The results suggest that the low frequency of dumping and diarrhea after highly selective vagotomy is offset by a high recurrence rate, and according to Visick grading, a complementary relation exists between recurrence and post-vagotomy symptoms in surgery for duodenal ulcer.

4511 GASTRIC-ACID OUTPUT, PEPSIN OUTPUT, AND LEAN BODY MASS IN NORMAL AND DUODENAL-ULCER SUBJECTS. *(E.)* Elder, J. B.; Smith, I. S. (R. Infirm., Manchester, England). *Lancet* 1(7914): 1000-1003, 1975.

The relation of pepsin output to gastric acid output and to lean body mass were investigated in 13 normal subjects and 40 duodenal ulcer patients. Peak pepsin output was stimulated by insulin-induced hypoglycemia and the enzyme was assayed by Piper's method. Peak acid output was determined following pentagastrin (6 µg/kg, s.c.). Pepsin output correlated significantly with acid output in normal subjects, and also showed good correlation with lean body mass. In the duodenal ulcer patients, there was no significant overall correlation of pepsin output with acid output or with lean body mass; however, based on the ratios of the three variables, the ulcer patients were separated in two groups whose ratios appeared to correlate with their symptomatic state at time of testing: pepsin output/mEq acid/kg lean body mass was significantly greater for patients in relapse than for patients in remission and for the normal group. The results suggest that both acid and pepsin may be important factors in inducing relapse in duodenal ulcer patients, and that pepsin output studies may prove helpful in understanding pathogenesis of relapse.

4512 SULFHYDRYL COMPOUNDS OF THE GASTRIC MUCOSA IN PATIENTS WITH PEPTIC ULCER. *(Rus.)* Samson, E. I.; Gaidichuk, S. T. (Chernovitsy Med. Inst., USSR). *Vrach. Delo* (1):12-15, 1975.

Sulfhydryl compounds were studied in 35 patients with peptic ulcer at the time of acute and moderate aggravation of the disease. Nine patients had normal structure of the mucosa; 24 had surface gastritis; in two patients peptic glands were affected but there was no evidence of atrophy. Acidity was elevated in 28 (pH below 1.5); normal in six (pH = 1.5 - 2.4); and low in one. It was demonstrated that in cases with normal mucosa and surface gastritis, sulfhydryl compounds were present in the basal membrane of surface epithelium and gastric fossae. The apical areas of both the surface epithelium and fossae were free from sulfhydryl compounds. In patients with marked morphological changes in the mucosa, sulfhydryl compounds were observed in the surface epithelium. There was evidence of faint staining in the epithelia of basal membrane and gastric fossae. A correlation was established between the intensity of staining of the parietal cells and elevated acidity. It is concluded that the distribution of sulfhydryl compounds in gastric mucosa of peptic ulcer patients correlates with the type of concomitant gastritis. It is suggested that sulfhydryl compounds may be involved in acid production.

SMALL INTESTINE

4540 INTESTINAL ENTEROKINASE DEFICIENCY. OCCURRENCE IN TWO SIBS AND AGE DEPENDENCY OF CLINICAL EXPRESSION. *(E.)* Haworth, J. C.; Hadorn,B.; Gourley, B.; Prasad, A.; Troesch, V. (Health Sci. Cent., Winnipeg, Canada). *Arch. Dis. Child.* 50(4):277-282, 1975.

Intestinal enterokinase deficiency in two siblings is described. The parents were not related, were healthy and free of gastrointestinal symptoms. A boy (6 weeks old) failed to gain weight and had vomiting, diarrhea, edema, hypoproteinemia, and anemia in early infancy. His duodenal juice contained very low or no proteolytic enzyme activity, which increased markedly after addition of enterokinase. He was treated with a regular diet with pancreatic extract and gained weight rapidly. At 44 months of age, he was normal, apart from some developmental delay, and no longer required pancreatic extract. The boy's older sister, who had similar symptoms in early infancy but then grew normally, had the same abnormality in her duodenal juice when seen at 4 yr. Enterokinase activity was virtually absent in the duodenal mucosa of both patients. Duodenal biopsies showed that the mucosal morphology was normal in both children. It is suggested that enterokinase deficiency is an inherited congenital defect and not the result of mucosal damage. Affected patients may show spontaneous improvement and normal growth after the age of 6-12 months. This phenomenon may be related to the decreasing growth velocity during the first 2 yr of life and the concomitant decrease in protein requirements/U body weight.

4541 INFLAMMATORY PSEUDOTUMORS (INFLAMMATORY FIBROUS POLYPS) OF THE SMALL INTESTINE: A CLINICOPATHOLOGIC STUDY. *(E.)* LiVolsi, V. A.; Perzin, K. H. (Coll. Physicians Surg., Columbia Univ., New York, N.Y.). *Am. J. Dig. Dis.* 20(4):325-336, 1975.

The clinical and pathologic features of 25 inflammatory pseudotumors of the small intestine are reported. For each specimen, pathology protocols, microscopic slides, and clinical records were reviewed. The group included nine males and 15 females (sex was unknown in one case) ranging in age from 6-86 yr (three patients were identified as adults only). In 16 patients, the diagnosis of small-intestinal obstruction, probably due to neoplasm, was made. The other patients were investigated for other reasons. All 25 patients underwent exploratory laparotomy. Sixteen lesions were found in the ileum and two in the jejunum. Intussusception was found associated with nine of 16 ileal lesions, with one of two jejunal tumors and with four cases in which the exact location of the lesion was unspecified. All 22 patients with lesions of the ileum or jejunum were treated by resection of the involved bowel segment. Of three patients with duodenal lesions, one underwent partial gastrectomy, one had a local excision of a duodenal nodule, and one was biopsied *via* a duodenotomy. Histologically, many cell types were noted in all these cases: fibrocytes, histiocytes, lymphocytes, scattered plasma cells, endothelial cells, leukocytes, and eosinophils. Mucosal involvement was found in 22 specimens. The etiology of the intestinal pseudotumor is unknown. No specific symptoms, laboratory tests, or x-rays established the diagnosis preoperatively. Even at laparotomy, the differential diagnoses included various neoplasms; only by histologic examination could the correct diagnosis be made. Following resection of the involved segment of small intestine, prognosis appears excellent. None of the patients for whom follow-up information was available had a recurrence of disease. It is suggested that intestinal pseudotumors may represent an exuberant granulation tissue response to mucosal ulceration.

4542 THERAPEUTIC CONSIDERATIONS REGARDING 75 PERFORATIONS OF THE SMALL INTESTINE. *(Fr.)* Spay, G. (No affil.). *Lyon Chir.* 71(1):34-38, 1975.

During 17 months in Kabul, Afghanistan, 55 cases of ileal perforation were observed including: 31 perforations due to typhoid; eight to *Ascaris*; three to multiple causes which included *Ascaris* in all three, typhoid in two and intestinal constriction of unknown etiology in the third; one case was due to stress; seven were of indeterminate etiology; and five unclassifiable due to incomplete records. Overall, the mortality rate was 37%, excluding three cases treated very recently. The patients ranged in age from 1.5 to 70 yr with most aged from 10-20 yr. The peak seasons for the perforations were in July, the rainy season following the Indian monsoon, and November, the dry period. Excision and suture was practiced in 13 cases, with success in 77%. This seems to be the optimum treatment for younger patients regardless of etiology. Exteriorization was practiced in 12 cases with only 42% success. This technique seems advisable with reservation in serious cases of typhoid in younger patients. Resection and temporary ileostomy was practiced 25 times, with 64% success. In 17 months in Dakar, Senegal, 20 cases of perforations were seen. They included one confirmed case of typhoid; five of multiple etiology with *Ascaris* in all five; nine of indeterminate etiology, of which six were suspected typhoid; one each with tuberculosis and excessive cortisone treatments; and three unclassifiable cases. The overall mortality was 50%. Simple suture in 13 cases produced 54% success and resection with anastomosis in four cases produced 50% success. Of the verified or strongly suspected cases of typhoid perforation, the mortality in the Kabul cases was 26%, compared with 33% for the Dakar cases. In general, simple suture is the preferred treatment and particularly favors the prognosis when the patient is seen less than a week after the onset of symptoms. Resection with terminal ileostomy should be reserved for the more serious cases.

4543 INTESTINAL LYMPHANGIECTASIA. LONG-TERM RESULTS WITH MCT DIET. *(E.)* Tift, W. L.; Lloyd, J. K. (Inst. Child Health, London, England). *Arch. Dis. Child.* 50(4):269-276, 1975.

The clinical course of six children with primary intestinal lymphangiectasia who were treated with low fat medium chain triglyceride-supplemented diets for 3-8 yr (four for longer than 5 yr) is described. All children showed rapid and sustained improvement in dependent edema; the asymmetrical edema, resulting from peripheral lymphatic anomalies, was unaffected by dietary and diuretic therapy. The low lymphocyte counts and reduced serum concentrations of albumin and IgG continued on the medium chain triglyceride diet. Laboratory tests indicated continuing chyle leak. Deliberate attempts to relax the restriction of dietary long chain fats were made in four patients. In three, diarrhea consistently recurred within 2-3 weeks of the introduction of a modest amount of long chain fat; two children also developed dependent edema and one ascites. In all three, symptoms subsided with the return to the medium chain triglyceride diet. It is claimed that laboratory evidence of continuing chyle leak does not indicate that treatment has no effect; return of biochemical findings to normal should suggest re-evaluation of the patient to determine whether the chyle leak has ceased, as occurred in one of six children in this group. For the majority of patients, however, it is likely that excessive gastrointestinal protein loss will continue. It is concluded that if such children are to achieve their optimum growth rate, it is necessary to continue a strict low-fat diet, supplemented with medium-chain triglycerides, at least until after puberty.

4544 INTESTINAL LYMPHANGIECTASIA: A REAPPRAISAL. *(E.)* Vardy, P. A.; Lebenthal, E.; Scwachman, H. (Child. Hosp. Med. Cent., Boston, Mass.). *Pediatrics* 55(6):842-852, 1975.

Fifteen children (nine boys and six girls) seen between 1960-1974 with histologically proven intestinal lymphangiectasia (IL) were analyzed retrospectively by clinical, laboratory, radiologic, and histologic criteria. Remissions occurred in most patients and none died. Exacerbations occurred in five children. Diarrhea was present in 14 cases and 13 patients presented before the age of 3 yr. Vomiting occurred in eight patients and growth retardation in seven. Four children had associated peripheral lymphedema and two of these had a family history of lymphedema; both had affected fathers and one had affected siblings and paternal cousins. Seven had hypoproteinemic edema and four of these suffered from hypocalcemic seizures. Chylous effusions were present in five; hypoproteinemia was present in 12 although five had no hypoalbuminemic edema. Six had lymphopenia which was related to the severity of the disease and was the last abnormality to disappear after clinical remission. Upper gastrointestinal tract series were performed in 13 children and had diagnostic supportive value in seven. Six children had two or more small intestinal biopsies done; all showed great variation from one examination to the other, ranging from a normal appearance to severe changes. Lymphatic block may occur at different sites: in the lamina propria only, generalized (lamina propria, submucosa, serosa, and mesentery), or conversely in the mesentery alone with minimal changes in the lamina propria. In three patients i.v. hyperalimentation was necessary. Specific treatment with a high-protein, low-fat diet with added medium-chain triglyceride is valuable. Surgical resection was of benefit in one patient and anastomosis of mesenteric to paraaortic lymph nodes in another. The data indicate that intestinal lymphangiectasia is more common than has been suspected and that the condition may vary widely in its manifestations and severity.

4545 BLEEDING MECKEL'S DIVERTICULUM DIAGNOSED BY ARTERIOGRAPHY AND RADIOISOTOPE IMAGING. *(E.)* Eisenberg, D.; Sherwood, C. E. (Highland Hosp., Rochester, N.Y.). *Am. J. Dig. Dis.* 20(6):573-576, 1975.

A 24-yr-old man with massive intestinal bleeding from a Meckel's diverticulum was diagnosed preoperatively by both abdominal arteriography and radioisotope imaging with technetium pertechnetate. A superior mesenteric arteriogram demonstrated pooling of contrast medium in the region of the distal ileum, to the right of the sacrum. The follow-up technetium imaging study showed accumulation of radioactivity corresponding to the angiographic pooling. At laparotomy, a large diverticulum of the ileum was found which contained ectopic gastric mucosa. The diverticulum and a short ileal segment were resected and an end-to-end anastomosis was performed. The surgical specimen revealed superficial erosion and ulceration of the ileal-bowel mucosa immediately adjacent to the diverticulum. When a bleeding Meckel's diverticulum is present, selective mesenteric artery arteriography may reveal either a localized area of vascularity in the right lower quadrant representing a richly vascular gastric tissue or puddling of contrast media near the site of active bleeding. Both these features existe in the present case The technetium pertechnetate ion is concentrated in functional ectopic tissue as well as in the stomach. Imaging is best performed with a gamma camera. False-negative findings in abdominal arteriography and technetium imaging may be caused by faulty technique or insufficient secretory gastric mucosa within the Meckel's diverticulum. False-positive findings have been reported n association with intestinal hemangiomas, aneurysms, and intestinal ulceration. Both examinations ppear to be promising adjuncts for the preoperaive diagnosis of bleeding Meckel's diverticulum.

SMALL INTESTINE

Malabsorption

4602 CONFIRMING PERSISTENCE OF GLUTEN INTOLERANCE IN CHILDREN DIAGNOSED AS HAVING COELIAC DISEASE IN INFANCY: USEFULNESS OF ONE-HOUR BLOOD XYLOSE TEST. *(E.)* Rolles, C. J.; Anderson, C. M.; McNeish, A. S. (Inst. Child Health, Univ. Birmingham, England). *Arch. Dis. Child.* 50(4): 259-263, 1975.

A p.o. gluten challenge (20 g/day) was given to 16 children diagnosed as having celiac disease when aged 3-11 months and who had been treated with a gluten-free diet for periods of 1 month to 5 yr. Xylose malabsorption was demonstrated in 15 children by a fall in the 1-hr blood xylose level within 1-28 days after gluten challenge. The fall tended to be more rapid in children who had been on a gluten-free diet for less than 6 months and who had residual abnormalities in the jejunum. However, xylose malabsorption was rapidly produced in four children who had been on a gluten-free diet for 7-10 months, including two with a normal prechallenge jejunal histology. One child, with a persistently normal 1-hr blood xylose test after gluten challenge for 3 months, had normal absorption and normal jejunal histology after 18 months on a gluten-containing diet; she is considered not to have celiac disease. These results demonstrate that the 1-hr blood xylose test before and after gluten challenge is helpful in confirming the persistence of celiac disease diagnosed in infancy.

4603 MALABSORPTION SYNDROME WITH COW'S MILK INTOLERANCE: CLINICAL FINDINGS AND COURSE IN 54 CASES.

(E.) Kuitunen, P.; Visakorpi, J. K.; Savilahti, E.; Pelkonen, P. (Child. Hosp., Univ. Helsinki, Finland). *Arch. Dis. Child.* 50(5): 351-356, 1975.

Clinical data are reported for 54 consecutive infants (25 boys and 29 girls) presenting with the malabsorption syndrome and cow's milk intolerance over a 10-yr period. All patients (mean age on admission, 15 weeks) had diarrhea, most had vomiting, and about 20% had atopic eczema and recurrent respiratory infections. Laboratory investigations revealed lactose malabsorption in about 1/2 the patients, raised serum IgA in 37 of 50, and precipitins to cow's milk in 32 of 49. Jejunal biopsy often showed severe mucosal damage of the type seen in celiac disease, and in about 1/2 the cases the mucosa was flat. The patients did well on human milk but reacted clinically to cow's milk challenge, either in a few hrs (28 cases) or gradually during 3-4 weeks (26); in some patients an initial rapid and a later slow reaction was discernible. Clinical symptoms of cow's milk intolerance disappeared at about age 1 yr, when 81% had normal fecal fat but only 29% a normal proximal jejunal mucosa. Positive reactions to cow's milk protein fractions were most frequent with β-lactoglobulin and casein. Sensitivity to cow's milk was also associated with intolerance to other food proteins such as soya and wheat. Of the 42 patients followed for 2 yr on a gluten-containing diet, 37 have a normal or nearly normal jejunal mucosa and 5 (12%) have subtotal villous atrophy indicative of celiac disease. It is concluded that the malabsorption syndrome with cow's milk intolerance is a clear-cut clinical entity. However, the symptomatology, results of laboratory tests, and jejunal biopsy findings closely resemble those of other entities where damage to the intestinal mucosa causes a malabsorption syndrome. Follow-up studies indicate that the disease is transient, but in about 10% of patients the primary disorder is celiac disease.

4604 ENTEROTOXIGENIC INTESTINAL BACTERIA IN TROPICAL SPRUE. II. EFFECT OF THE BACTERIA AND THEIR ENTEROTOXINS ON INTESTINAL STRUCTURE.

(E.) Klipstein, F. A.; Schenk, E. A. (Trop. Malabs. Unit, Univ. Rochester, New York). *Gastroenterology* 68(4):642-655, 1975.

Randomly selected strains of the predominant coliform bacteria (3 serotypes of *Kiebsiella pneumoniae* and a strain of *Enterobacter cloacae)* isolated from each of 4 Puerto Ricans with tropical sprue were examined for their effect on intestinal structure in the ileal loop model of 34 rabbits. The viable bacteria did not evoke a fluid response, invade the mucosa, or cause changes in villus architecture; but they did result in the formation of a luminal exudate consisting of mucin, necrotic epithelial cells, bacteria, and epithelial cell enzymes. Cell-free broth filtrates of bacterial growth of all 4 strains produced an increasingly positive fluid response from 2-18 hr and progressively more severe structural changes consisting of shortening and blunting of the villi, infiltration predominantly by mononuclear cells, and submucosal congestion. Equally hypermolar control preparations of broth-free medium without bacterial growth and cell-free broth filtrates of a nontoxigenic strain of *Escherichia coli* failed to induce these abnormalities. These observations indicate that the coliform bacteria tested elaborate a toxic product, presumably an enterotoxin, which produces structural and functional changes of the intestinal mucosa resembling those present in tropical sprue.

4605 ILEAL FUNCTION IN PATIENTS WITH UNTREATED ADULT COELIAC DISEASE.

(E.) Silk, D. B. A.; Kumar, P. J.; Webb, J. P. W.; Lane, A. E.; Clark, M. L.; Dawson, A. M. (St. Bartholomew's Hosp., London, England). *Gut* 16(4):261-267, 1975.

Jejunal and ileal absorption of glucose, water, and electrolytes in 8 patients (mean age, 38 yr) with untreated adult celiac disease was investigated with a double-lumen perfusion technique. Correct positioning of the tube was confirmed by measuring the differential jejunal and ileal handling of bicarbonate. The 8 patients and 8 controls (mean age, 40 yr) were perfused with an isotonic electrolyte solution containing 50 mM glucose and 25 mM bicarbonate. Compared with the controls, the celiac patients had significantly impaired jejunal absorption of glucose, water, sodium, and chloride. In contrast, the celiac patients had normal ileal glucose and water absorption and significantly increased ileal sodium and chloride absorption compared with the controls. Evidence for ileal adaptation was found in 3 patients who had absorptive values outside 2 standard deviations of the normal mean. These patients had greater ileal surface cell heights than the other celiac patients and tended to have taller villi than the remaining celiacs. This study indicates that the distal small intestine in celiac disease has the ability to adapt to the damage and loss of absorptive capacity in the proximal small intestine. The enhanced ileal function in celiac disease may be due to distal ileal mucosal cell hyperplasia ocurring in response to the jejunal mucosal lesion.

606 SMALL INTESTINAL BIOPSY IN COW'S MILK PROTEIN ALLERGY IN INFANCY. *(E.)* Fontaine,
. L.; Navarro, J. (Trousseau Hosp., Paris, France).
rch. Dis. Child. 50(5):357-362, 1975.

ntestinal biopsies were performed in 31 infants
19 girls and 12 boys, aged 3-30 months) with cow's
ilk protein intolerance. Mucosal damage was
bserved in 30 cases, including 4 infants biopsied
hile on a milk-free diet. Partial villous atrophy
as present in 25 cases, subtotal villous atrophy
n 1, and slight histological lesions in 4. Of
he 25 cases of partial villous atrophy, 5 were
rade I; 12, Grade II; and 8, Grade III. Complete
ucosal recovery occurred in 4 children after 3-13
onths on a milk-free diet. It is concluded that
he mucosal damage seen in cow's milk protein allergy
s induced by cow's milk, though the mechanism re-
ains unknown.

607 CELL-MEDIATED IMMUNITY TO GLIADIN WITHIN THE SMALL-INTESTINAL MUCOSA IN COELIAC
ISEASE. *(E.)* Ferguson, A.; MacDonald, T. T.;
cClure, J. P.; Holden, R. J. (West. Infirm.,
lasgow, Scotland). *Lancet* (7912):895-897, 1975.

n an attempt to demonstrate local cell-mediated
mmunity to gliadin in patients with celiac disease,
ragments of jejunal biopsy specimens were cultured
n the presence or absence of α-gliadin and the
ulture medium assayed for its capacity to inhibit
igration of normal human peripheral blood leukocytes
i.e., for a migration-inhibition factor MIF). No
IF activity was detected in the culture medium
hen biopsy specimens from 15 patients with celiac
isease or from 29 controls were cultured without
dded gliadin. The addition of α-gliadin (0.5 mg/
l) to the culture system did not result in MIF
ecretion by nonceliac mucosa or by the mucosa
rom 2 patients with celiac disease treated with
gluten-free diet. However, when biopsy specimens
rom 6 patients with untreated celiac disease were
ultured with α-gliadin, they secreted a factor
nto the culture medium which significantly in-
ibited the migration of normal human leukocytes
>30% inhibition in 5 of the 6 cases). These
indings suggest that there is a population of
ymphocytes which are sensitized to gliadin in the
ntestinal mucosa of patients with untreated celiac
isease. They support the theory that a local
ell-mediated immune reaction may be the cause of
illous atrophy and crypt hyperplasia in celiac
isease.

608 CHARACTERISTICS OF CARBOHYDRATE ABSORPTION AND METABOLISM IN PREMATURE AND NEWBORN
NFANTS. *(Ger.)* Beyreiss, K.; Rautenbach, M.; Will-
erodt, H.; Schone, S.; Al-Rebate, I. (Pediatr. Clin.,
arl Marx Univ., Leipzig, Germany). *Wiss. Z. Fried-*
ich Schiller Univ. Jena Math. Naturwiss. Reihe 21
(4):683-693, 1972.

arameters of the absorption and conversion of the
ructose and galactose were studied using blood level
inetic procedures in premature, newborn, nursing
infants, and healthy children and adults. Total clearance, absorption rate (Dost), and the concentration of the hexoses in blood, urine and stool were measured by specific methods. Characteristics of active monosaccharide absorption with adequate transport capacity in neonates was demonstrated in the first days of life. The low absorption rates of fructose in all age groups were caused in part by transformation in the small intestinal mucosa. For galactose also, a conversion upon passage through the intestinal mucosa was assumed with neonates and nursing infants in contrast to adults. The conversion rate of fructose was depressed in the neonatal period independent of maturity and attained the parameters of later infant age in the third week of life. In contrast, the optimal conversion range and the maximum conversion capacity for galactose with newborns was considerably greater than with adults. True premature infants showed hindered conversion of galactose only in the first days of life as compared to matured neonates. In the neonatal period, galactose raises the glucose concentration in the blood independent of the entrance location; fructose, however, raises blood glucose concentration only when given p.o.

4609 ABNORMALITIES OF SERUM CHOLECYSTOKININ AND GALLBLADDER EMPTYING IN CELIAC DISEASE. *(E.)* Low-Beer, T. S.; Harvey, R. F.; Davies, E. R.; Read, A. E. (R. Infirm., Bristol, England). *N. Engl. J. Med.* 292(18):961-963, 1975.

The relation between gallbladder contraction and serum cholecystokinin levels after a fatty meal was studied in 10 patients (7 men and 3 women, average age 58 yr) with adult celiac disease and 10 controls with no history of upper-intestinal tract disease. After an overnight fast, each subject drank 60 ml of a flavored emulsion of 33% peanut oil. Serum cholecystokinin levels, at various intervals after consumption of the emulsion, were measured by a radioimmunoassay technique; gallbladder emptying was monitored continuously *via* isotope cholecystography. In 9 of the patients, the fasting serum cholecystokinin levels were significantly raised over control values. However, the peak serum cholecystokinin levels and the increments in serum cholecystokinin after fat intake were lower in the celiac disease patients. Emptying of the gallbladder was less complete in the patients than in the controls and the onset of gallbladder emptying was significantly delayed in the former. The elevated fasting serum cholecystokinin levels in the celiac disease patients may have resulted from increased secretion of the hormone by the enterochomaffin-like cells in the small-bowel mucosa; this might result from a disturbance in some regulatory mechanism for hormone secretion. Available evidence suggests that the gallbladder in celiac disease is less responsive than normal to the action of endogenous cholecystokinin. The pathogenesis of the diminished pancreatic exocrine response which has been noted in celiac disease is probably similar to that of the diminished gallbladder contraction. Resistance to the action of cholecystokinin in both cases may in some way be related to the presence of constantly high levels of this hormone in the blood.

4610 ULTRASTRUCTURAL AND HISTOCHEMICAL STUDY OF THE BACTERIAL DESTRUCTION IN TWO CASES OF WHIPPLE'S DISEASE.

(Fr.) Chamlian, A.; Casanova, P.; Cougard, A.; Mathieu, B. (Fac. Med., Marseille, France). *Ann. Anat. Pathol. (Paris)* 19(2):221-230, 1974.

The destruction of bacteria in two men aged 40 and 45 with Whipple's disease was studied by examination of specimens of jejunal mucosa obtained by peroral biopsy from the duodeno-jejunal flexure, both before and after a 7-month course of treatment which established remission. In one case the treatment was 1 g/day erythromycin, and in the other case it was 0.2 g/day doxycyclin. In the untreated cases, bacteria were concentrated in the mucous chorion of the intestinal villi and may accumulate under the basal epithelial basal membrane at the apex of the villi. Bacteria are often located around fatty particles and are often vacuolized. When they penetrate the villous chorion, they are attacked and digested by macrophages. At the inferior part of the mucosa, between the glandular cul-de-sacs and the muscularis mucosae, the macrophages seem to be less active than at the top of the villi, as they do not contain bacterial bodies but rather granular or filamentous material. During remission, bacteria are no longer visible, and the residual macrophages contain lamellate or granular material. In the untreated disease, the macrophages at the top of the villi are strongly colored by para-aminosalicylic acid which indicates the presence of neutral mucopolysaccharides. They have no affinity for colloidal iron, whereas the macrophages at the inferior part of the mucosa have the opposite affinities. During remission, the few remaining macrophages at the top of the villi react with both para-aminosalicylic acid and colloidal iron, while the more numerous deeper macrophages contain occasional particles reactive with para-aminosalicylic acid and many voluminous vacuoles with a moderate reaction to colloidal iron. The para-aminosalicylic acid undoubtedly is made to react by the mucopeptides contained in the bacterial wall. Acid phosphatase activity is great in the superficial macrophages and moderate in the deeper macrophages in the untreated disease. Apparently, macrophages at the top of the villi ingest material and migrate deeper into the mucosa as they digest it.

4611 CLINICAL, IMMUNOLOGICAL AND ELECTRON MICROSCOPE STUDIES OF WHIPPLE'S DISEASE.

(Ger.) Buchholz, K.; Maintz, J.; Otto, H. F. (Hamberg-Heidberg Hosp., Germany). *Klin. Wochenschr.* 52(14):672-677, 1974.

An unusual course of Whipple's disease is reported. The patient (male, 57 yr) had a stomach resection for bleeding ulcer about 1/2 year prior to admission and was in generally poor health; malabsorption was suspected. Small intestinal biopsy was performed and Whipple's disease was confirmed on the basis of light and electron microscope evidence. Treatment with tetracycline (Vibramycin, 100 mg/day) resulted in rapid disappearance of clinical symptoms, weight gain, and return to normal levels of blood chemical data. A persistent clinical remission was noted 1 yr later with continued antibiotic therapy. As early as 5 months after institution of therapy multiple control biopsies showed a strong and progressive collagen formation of the stratum propium mucosae, especially in the pericellular region and near the epithelial basal membrane. The number of lymphocytes, plasma cells and interepithelial lymphoid round cells increased considerably. Immunologically, the serum complement (C_3-fraction) was decreased. Immunohistologically, subepithelial and interepithelial cells were found after incubation with the patient's serum showing a cellular-cytoplasmic fluorescence with anti-complement. These findings indicate a hyper-reactive mechanism possibly leading to induction of a cellular immune process.

4612 HISTOCHEMICAL STUDY OF ENTEROKINASE IN DUODENAL AND JEJUNAL BIOPSIES FROM CHILDREN WITH MALABSORPTION SYNDROME.

(Cz.) Lojda, Z.; Jodl, J. (Fac. Gen. Med., Charles Univ., Prague, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 28(8):532-539, 1974.

Since histological studies of unaffected parts of the duodenum and jejunum, removed from two patients at surgery, demonstrated that enterokinase activity is much higher in the duodenum than in the jejunum, duodenal biopsies were taken from children with a variety of malabsorption syndromes. Using a method described previously, the enterokinase activity in duodenal biopsies taken from the mid-duodenum in patients without gastrointestinal symptoms reached a maximum in the enterocytes after 2 hr of incubation and was so high on the top and along the sides of the villi that a diffuse reaction product was seen as far as the lamina propria. After this incubation period, the cytoplasm of Brunner's glands was stained only nonspecifically by the diazo reaction and the enterokinase activity in the epithelium of the crypts was very low. Enterokinase activity in duodenal biopsies from three children with pancreatogenic malabsorption was similar to that found in five children with no evidence of gastrointestinal disease. Normal enterokinase activities were also found in duodenal biopsies from two children with lactase deficiency, as diagnosed by jejunal biopsies, and from five of nine children with diarrhea of unknown etiology; enterokinase activities were decreased in the remaining four cases. Only moderate irregularities in mucosal relief and moderate inflammatory changes were observed in these cases of diarrhea. Duodenal enterokinase activities were normal in four and decreased in eight patients with cow's milk intolerance and normal lactase activities. No enterokinase at all was present in the duodenum of the remaining four patients, even when biopsies were repeated. Duodenal enterokinase activities were normal in 12 and decreased in 12 children with manifest celiac disease. Of seven patients with celiac disease in remission, five exhibited normal duodenal enterokinase activity and two, decreased activity. In four cases (one patient each with disaccharide deficiency, cow's milk intolerance, manifest celiac disease and celiac disease in remission), biopsies from the distal duodenum had no evidence of enterokinase activity.

LARGE INTESTINE

4645 NEW TECHNIQUE FOR THE STUDY OF DEFECATION BY MANOMETRY: ITS APPLICATION IN THE DIFFERENTIAL DIAGNOSIS OF MEGARECTUM. *(Fr.)* Hata, Y.; Duhamel, B.; Labarraque, J. P. (Saint-Denis Hosp. Cent., France). *Ann. Chir. Infant.* 15(2):77-86, 1974.

A simple manometric technique was used to visualize the rectoanal inhibitory reflex in 4 normal 3-yr-old children. A balloon-tipped probe was inserted in the barium-filled rectum until the ballon reached the upper portion of the internal sphincter. The balloon was then rapidly inflated while a series of profile X-rays was taken of the seated child. A minimum balloon volume of 10cm^3 was necessary to stimulate opening of the anal canal, which was widest 3-4 sec after stimulation and closed again after 7 sec. A 4-yr-old girl with hypoganglionic megarectum needed a balloon volume of 50cm^3 to open the canal, which then took 10 sec to close. This technique has shown that the internal and external anal sphincters react together, and not sequentially, on dilatation of the rectum. When perfected, it should prove a valuable aid in the differential diagnosis of different types of megarectum.

4646 CEA AS A MONITOR OF GASTROINTESTINAL MALIGNANCY. *(E.)* Holyoke, E. D.; Ming Chu, T.; Murphy, G. P. (Roswell Park Mem. Inst., Buffalo, N. Y.). *Cancer* 35(3):830-836, 1975.

Patients (94) with carcinoma of the colon were studied to determine the reliability of carcinoembryonic antigen (CEA) as a monitor of the malignancy. Determinations of plasma CEA levels were made over a 3-yr period using the Hansen assay, and simultaneous measurements of alkaline phosphatase were made. The CEA levels in 719 of 912 determinations accurately reflected the presence or absence of tumor. The assay detected 47 of 52 clinically clear-cut progressions; the CEA levels rose for 6-14 months in advance of clinical progression. False positive results were encountered in 10% of the patients. CEA levels responded to chemotherapy in close correlation with observed clinical course in the patients with metastatic disease. Initial pretherapy CEA values proved to be good prognostic indicators of disease course following complete resection; an initial CEA value less than 2.5 ng/ml plasma had recurrence of 1 in 120, a CEA greater than 7.0 ng/ml had recurrence of 7 in 9. CEA measurement was found to be as much as twice as sensitive as the alkaline phosphatase test, particularly for metastatic tumor in the liver. The results indicate that CEA can be used as a monitor of patients with colon carcinoma providing its limitations are understood.

4647 METASTATIC CARCINOMA SIMULATING INFLAMMATORY COLITIS. *(E.)* Meyers, M. A.; Oliphant, M.; Teixidor, H.; Weiser, P. (New York Hosp.-

Cornell Univ. Med. Cent., N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(1):74-83, 1975.

Cases (12) of metastatic carcinoma which were initially considered as ulcerative or granulomatous colitis clinically and roentgenologically were studied to establish distinguishing features of the malignancies. Characteristic roentgen findings included mucosal thickening, nodular masses, multiple and eccentric strictures, asymmetric involvement, pseudosacculations, spiculations of contour, and frequent associated terminal ileal involvement. Discrete changes and the distribution of colonic involvement distinguished metastatic disease from inflammatory colitis; the specific features were dependent upon pathways of spread, growth characteristics, and local tissue response. Where differentiation is difficult, deep biopsies, histologic documentation or other roentgenographic studies are suggested. Recognition of the characteristic roentgenologic changes is of great clinical importance and leads to a search for the primary neoplasm or establishes the diagnosis of the disease.

4648 MESOCOLIC LYMPH NODE HISTOLOGY IS AN IMPORTANT PROGNOSTIC INDICATOR FOR PATIENTS WITH CARCINOMA OF THE SIGMOID COLON: AN IMMUNOMORPHOLOGIC STUDY. *(E.)* Patt, D. J.; Brynes, R. K.; Vardiman, J. W.; Coppleson, L. W. (Univ. Chicago Hosp. Clin., Ill.). *Cancer* 35(5):1388-1397, 1975.

Histologic changes in human lymph nodes draining adenocarcinomas of the sigmoid colon were evaluated and the prognostic significance of the observed changes were assessed. Cases of adenocarcinoma of the sigmoid colon (36) treated between 1965 and 1968 were studied. Lymph nodes were examined for germinal center activity, sinus histiocytosis, and paracortical activity. Patients whose lymph nodes showed morphological evidence of cell-mediated immunity, either by an increased number of paracortical immunoblasts or sinus histiocytosis, survived significantly longer than those whose lymph nodes showed no such changes. Patients whose lymph nodes showed simultaneous paracortical activity and sinus histiocytosis had the best survival of all. Of that group, 11 of 13 lived 5 yr or more after surgery without signs of recurrent tumor. Germinal center activity was not a significant factor in prognosis. Favorable lymph node histology did not significantly correlate with the modified Duke's classification. The observations support the hypothesis that the immunoblasts observed within the paracortical region of draining lymph nodes are a morphological manifestation of an antitumor T-cell-mediated immune response, and those patients whose lymph nodes have a morphological pattern compatible with a cell-mediated immune response have the best prognosis.

4649 PAPILLARY ADENOMAS OF THE COLON AND RECTUM: A TWELVE-YEAR REVIEW. *(E.)* Jahadi, M. R.; Bailey, W. (Baylor Univ. Med. Cent., Dallas, Tex.). *Dis. Colon Rectum* 18(3):249-253, 1975.

A retrospective study was made to review 12-yr experience with papillary adenomas of the colon and rectum and to evaluate methods of management. Between 1960 and 1972, 185 patients (101 women, 84 men) with papillary adenomas of the colon and rectum were treated; the average age was 63 yr. Of these patients, 40% had rectal bleeding; 71% of the lesions occurred in the rectum and rectosigmoid. The lesions were malignant in 52% of cases; 9% of the patients died with metastatic carcinoma. The 5-yr survival rate was 75%. The results of the study indicate that a conservative approach to the surgical management of papillary adenoma of the colon and rectum should be encouraged, unless the tumor contains or is suspected to contain invasive carcinoma.

4650 APPENDICITIS. A CRITICAL REVIEW OF DIAGNOSIS AND TREATMENT IN 1,000 CASES. *(E.)* Lewis, F. R.; Holcroft, J. W.; Boey, J.; Dunphy, J. E. (San Francisco Gen. Hosp., Calif.). *Arch. Surg.* 110(5):677-684, 1975.

A retrospective analysis was made of 1,000 cases of appendicitis seen from 1963 to 1973 to provide demographic data, to elucidate reliable symptoms, signs, and laboratory studies, and to determine factors affecting morbidity and mortality of appendicitis. The overall negative appendectomy rate was 20%, but it exceeded 40% in women aged 20-40 yr. Nonsurgical lesions were the cause of 2/3 of the negative appendectomies; mesenteric adenitis, gastroenteritis, and abdominal pain of unknown cause accounted for 1/3 of the errors in females and 2/3 in males. Those diseases were best distinguished from appendicitis on the basis of temperature and white blood cell count. The remainder of errors in females were due to pelvic inflammatory disease or other gynecologic problems and were best distinguished from appendicitis on the basis of history and physical findings. The rate of perforation was 21% and the incidence of wound infection was 8.5%. Use of antibiotics did not affect wound infection rate, but they are clearly indicated in perforated appendicitis. Morbidity from appendicitis was primarily due to infection; it was noted that vertical incisions had a significantly higher incidence of infection than right lower quadrant oblique incisions. The authors express the need for improved accuracy in early diagnosis of appendicitis to reduce the rate of unnecessary appendectomy.

4651 ANORECTAL AND COLONIC MANOMETRY: NORMAL AND PATHOLOGICAL MOTOR ACTIVITY. *(Por.)* Habr-Gama, A.; Haberkorn, S.; Gama-Rodrigues, J. J.; Raia, A.; Bettarello, A. (Fac. Med., Univ. Sao Paulo, Brazil). *Arq. Gastroenterol. Sao Paulo* 11(4):201-216, 1974.

Analysis was made of 268 tracings of motor activity in the left colon and rectum (88 cases) or in the anorectal region (180 cases). Colonic manometry was performed on 15 normal controls, five patients with constipation, five with diarrhea, 48 with megacolon due to trypanosomiasis, and 15 with diverticula of the colon. Anorectal tracings were obtained from 15 normal children, 95 with constipation, 30 with congenital megacolon, 20 with malformations of the lumbosacral spine, and 20 patients with megacolon due to trypanosomiasis. Colonic manometry gave the best information on the physiopathology in many of these conditions and served as an aid in selecting methods of treatment. In chronic constipation, colonic motility was increased, suggesting that the use of antispasmodics would facilitate passage of stools. In diarrhea, segmental colonic contractions were decreased, suggesting that anticholinergics, rather than antispasmodics, should be employed. Colonic manometry also demonstrated that diverticula cause increased segmental pressures, primarily in the sigmoid. In uncomplicated forms of diverticulosis and at its onset a high-residue diet facilitates the passage of stools and might prevent the formation of segmental chambers which lead to diverticula. If this conservative therapy fails, sigmoidomyotomy might decrease intraluminal pressures. Megacolon due to trypanosomiasis was accompanied by dyskinesia and absence of the inhibitory reflex at the internal anal sphincter after rectal distention. On the basis of these findings, it is concluded that surgery only improves symptoms by removing the enlarged colon and correcting fecal stasis without having any effect on underlying physiological changes. In children with congenital megacolon, anorectal manometry helps to establish a differential diagnosis between constipation and congenital megacolon, even when the aganglionic segment is very short and a barium enema gives doubtful results. In children with various spinal malformations (sacral agenesis, meningocele, myelomeningocele, and occult spina bifida), anorectal manometry demonstrated whether pressures at the level of the internal anal sphincter were normal and whether this muscle could be used in training these children to develop a normal rhythm of evacuation.

4652 CLINICAL PATTERNS OF ABDOMINAL TUBERCULOSIS. *(E.)* Das, P.; Kumar, P.; Gupta, C. K.; Indrayan, A. (M.L.N. Med. Coll., Allahabad, India). *Am. J. Proctol.* 26(2):75-86, 1975.

To assess the value of various clinical features in the diagnosis of abdominal tuberculosis, 141 cases of abdominal tuberculosis were analyzed clinically and histopathologically. Clinical features were assessed based on the hospital records of the cases admitted between 1967 and 1971. The histological features were determined using 70 specimens obtained from 57 cases. On the basis of the histological examinations, it was difficult to differentiate tuberculous from nonspecific lesions of the bowel. The presence of frank caseation, giant cells, epithelioid cells, and round cells are indicative of tuberculosis, but a microscopic picture similar to a nonspecific type of inflammation may also be present in tuberculous infections of the bowel. In the cases examined, a preoperative clinical diagnosis was given in only 39% of the patients; 8.6% were admitted with acute abdomen and 53.9% were diagnosed with intestinal obstruction. The incidence of the disease increased between 11 and 20 yr of age, peaking between 21 and 30 yr. The female:male ratio was 2.4: 1. The commonest symptoms were generalized pain in and around the umbilical region, vomiting, and constipation; fever, weight loss, and anorexia were also common, and an associated pulmonary lesion was present in 5% of the patients. The most frequent physical signs were abdominal distension, tenderness, and abdominal lumps. Diarrhea was present in 17% of the cases, umbilical fistula in 2.5%, intraperitoneal abscess in 5%, and internal, perianal, and perirectal fistula in none. A diagnostic scoring system involving the allocation of points to parameters such as age, sex, symptoms, duration of symptoms, and signs has been devised; a score of 70 or above (maximum 100) is probably indicative of abdominal tuberculosis.

4653 MEGARECTUM IN CHILDREN: AN ANATOMICAL AND CLINICAL STUDY. *(Fr.)* Hata, Y.; Duhamel, B.; Pages, R.; Poirat, J. B.; Ripault, J. (Saint-Denis Hosp. Cent., France). *Ann. Chir. Infant.* 15(2):65-76, 1974.

Idiopathic megarectum was diagnosed and treated with anorectal sphincteromyectomy in 63 children. None of these patients had megarectum associated with anal imperforation, sacral agenesis, or spina bifida. Biopsies showed either abnormalities in the autonomic innervation of the juxta-anal segment of the rectum (19 cases), structural defects of the internal sphincter (15), or a combination of both abnormalities (19). No morphological abnormalities were detected in 10 cases. A statistical analysis of the date of onset of symptoms suggests that the disease is embryonic in origin. Sphincteromyectomy resulted in a complete cure in 54% of these children, a great improvement in 25%, some improvement in 10%, and no change in 11%. Most of the failures occurred in patients with abnormal innervation, and were later successfully treated with more extensive rectal surgery. The postoperative results were not dependent on age or on clinical or radiological features. This benign and effective method of diagnosis and treatment should be the initial surgical procedure in all patients with megarectum.

4654 AMMONIA AND UREA TRANSPORT BY THE EXCLUDED HUMAN COLON. *(E.)* Bown, R. L.; Gibson, J. A.; Fenton, J. C. B.; Snedden, W.; Clark, M. L.; Sladen, G. E. (St. Batholomew's Hosp., London, England). *Clin. Sci. Mol. Med.* 48(4):279-287, 1975.

Ammonia and urea transport across the colonic mucosa was studied in four subjects who had successfully undergone colonic exclusion for chronic hepatic encephalopathy. The colon was initially cleansed of fecal material and 24 hr later was perfused antiperistaltically with three isosmotic solutions containing 2 g/liter of the nonabsorbed marker polyethylene glycol. The peripheral venous blood was analyzed before perfusion and after the establishment of equilibrium conditions. In some cases, ammonium chloride or urea was added to the perfusion solutions or was infused i.v. Reduction of the luminal pH inhibited the net and unidirectional transport of ammonia from the lumen into the plasma, but the net absorption from high luminal concentrations persisted at low pH. Neither the addition of urea to the perfusate nor i.v. urea infusion produced a consistent increase in the colonic excretion of ammonia in the presence of amonnia-free perfusates. In one subject, i.v. infusion of $[^{15}N]$ ammonium chloride produced rapid labeling of the colonic effluent ammonia, and within 1 hr the specific enrichments of the ammonia in the effluent and in the arterial plasma were approximately equal. During perfusion with nitrogen-free solutions, only small amounts of urea appeared in the effluent, suggesting limited permeability of the colonic mucosa to urea. The results indicate that luminal acidification impairs net ammonia absorption from the colonic lumen and that ammonia either enters the lumen from the plasma or is generated within the lumen from urea or other sources. They also suggest that both ammonia and NH_4^+ diffuse across the colonic mucosa down electrochemical gradients and that the mucosa is considerably more permeable to ammonia than to NH_4^+. Exclusion of the colon appears to abolish the juxtamucosal conversion of urea into ammonia.

4655 RECTAL BIOPSY IN CLINDAMYCIN-ASSOCIATED COLITIS. AN ANALYSIS OF 23 CASES. *(E.)*

Sumner, H. W.; Tedesco, F. J. (Washington Univ. Sch. Med., St. Louis, Mo.). *Arch. Pathol.* 99(5):237-241, 1975.

The findings on rectal biopsy and proctoscope examinations in 23 cases of clindamycin-associated pseudomembranous colitis are summarized. The average age of the patients, 16 of whom were female, was 52 yr. The initial manifestations of colitis were diarrhea and abdominal pain, the average interval between the initiation of clindamycin therapy and onset of symptoms being 8 days. In 14 patients, clindamycin was administered orally (150 mg four times daily), in four it was administered i.v. (300-600 mg four times daily), and in five it was administered by both routes. The interval between the onset of symptoms and complete clinical resolution of the disease averaged 13 days; one patient died after 27 days. Therapy consisted of diphenoxylate hydrochloride with atropine sulfate and general supportive care. Stool cultures showed no growth of staphylococci or other enteric pathogens. On proctoscopic examination, discrete 2-5 mm raised plaques were seen adherent to an edematous, friable mucosa. Rectal biopsy showed pseudomembrane formation and inflammation of the underlying rectal mucosa. Necrosis of the surface epithelium was a frequent finding but no true ulcers were observed. The pseudomembrane was frequently observed to be dislodged from the mucosal surface. Vasculitis or thrombosis was not a feature in any case. Follow-up biopsies in four patients failed to show pseudomembranes and follow-up proctoscopic examinations showed no plaque-like lesions. While the pathologic and proctoscopic features of clindamycin-associated colitis are distinctive in the majority of cases, there are instances in which the disorder could be confused with ulcerative colitis. Proper diagnosis can be aided by awareness of the entity, repeated examinations when necessary, and communication between clinician and pathologist.

4656 BILE ACID EXCRETION AFTER PULL-THROUGH OPERATION FOR HIRSCHSPRUNG'S DISEASE. *(E.)*

Gaze, H.; Murphy, G. M.; Nelson, R.; Corkery, J. J.; Anderson, C. M. (Inst. Child Health, Univ. Birmingham, England). *Arch. Dis. Child.* 50(3):243-245, 1975.

To determine whether altered bile acid metabolism is involved in the production of chronic diarrhea after pull-through surgery for Hirschsprung's disease, the fecal and duodenal bile acids were studied in four patients suffering from diarrhea after such surgery. 3α-dehydrogenase and fluorimetry were used to determine the bile acid concentrations in three 24-hr fecal samples from each patient and in duodenal samples obtained after fasting and after i.v. pancreozymin administration. Fecal fat excretion was also determined, as was the bacterial content of the duodenal and gastric fluids. The fecal bile acids were elevated in all four children who had undergone the Soave pull-through operation in comparison with one child who had undergone colostomy for Hirschsprung's disease and 10 control children. In all five patients, the duodenal bile acid concentrations after pancreozymin stimulation were within normal limits. Bile acid analysis of the 'bile-rich' duodenal fluid obtained after pancreozymin stimulation in three of the pull-through patients indicated a marked reduction in the proportion of deoxycholic acid conjugates. In addition, two of these patients, who also had the highest fecal bile acid levels, showed an elevated ratio of glycine conjugated bile acids to taurine conjugated bile acids in the duodenal aspirate. The fecal fat levels and bacterial flora of the upper small intestine were normal in all cases. The results suggest colonic malabsorption of secondary bile acids in pull-through patients, but indicate that this is probably not the cause of the diarrhea and anal excoriation in these patients.

4657 A DOUBLE-BLIND COMPARISON OF INTENSIVE COURSE 5-FLUOROURACIL BY ORAL VS. INTRAVENOUS ROUTE IN THE TREATMENT OF COLORECTAL CARCINOMA. *(E.)*

Hahn, R. G.; Moertel, C. G.; Schutt, A. J.; Bruckner, H. W. (Mayo Clin. Mayo Found., Rochester, Minn.). *Cancer* 35(4):1031-1035, 1975.

The efficacy of p.o. and i.v. 5-fluorouracil (5-FU) administration in the treatment of colorectal carcinoma was studied using a randomized double-blind procedure. 5-FU was given p.o. (20 mg/kg/day) for 5 days to 47 patients with biopsy-proven metastatic adenocarcinoma of the colon and rectum; an i.v. dose of 13.5 mg/kg/day was given over the same period to 53 similar patients. To determine the effectiveness of the treatments, the patients were reevaluated at 5 and 10 weeks after the initiation of therapy. The blood levels of 5-FU were determined in 19 patients 15, 30, 45, 60, and 120 min posttreatment. There were no significant differences between the i.v.- and p.o.-treated patients in terms of toxic reactions to the drug; the gastrointestinal toxicity and stomatitis seen in each group did not require modification of the dosage and, although severe leukemia occurred in 31% of the patients, there were no drug-related deaths. With regard to the therapeutic results in the two groups, i.v. administration was associated with a nonsignificant increase in overall regression rate and a significant increase in the mean duration of response. Similar results were obtained when both groups of patients were analyzed for specific response of the metastatic hepatic disease. I.v. administration was also associated with a more rapid decline in the 5-FU concentrations in the blood. In addition, while the blood concentration curves were comparable among the different patients receiving i.v., 5-FU, there was a striking variability among different patients receiving the drug p.o. The results suggest that, when indicated, 5-FU therapy is best provided by the i.v. route of administration.

Ulcerative Colitis

4709 EFFECT OF A CHEMICALLY DEFINED LIQUID ELEMENTAL DIET ON COMPOSITION AND VOLUME OF ILEAL FISTULA DRAINAGE. *(E.)* Hill, G. L.; Mair, W. S. J.; Edwards, J. P.; Morgan, D. B.; Goligher, J. C. (Gen. Infirm., Leeds, England). *Gastorenterology* 68 (4):676-682, 1975.

The effect of an elemental diet on the quantity and composition of the ileal fistula drainage was studied in 10 patients with well-established ileostomies. During the first 4 days of the study period, the patients, all of whom were in good health, consumed a "normal" control diet. At the end of this period, the patients were put on a standard elemental diet which supplied the same amount of calories as the control diet. After 8 days on this diet, the patients were put on a 3-day regimen in which 2000 ml of water were taken in addition to the elemental diet. The water content in the feces and ileostomy fluid, the sodium and potassium contents in the urine and ileostomy fluid, and the urinary and ileostomy fluid volumes were measured throughout the study. The mean daily fecal output during the control period was 570 g; during the administration of the elemental diet the fecal output fell to 441 g ($P > 0.02$). In addition the output of sodium in the ileostomy fluid fell from 62.7 to 3.41 mEq ($P > 0.02$) and the output of potassium fell from 5.2 to 2.9 mEq ($P > 0.001$) during administration of the elemental diet, and the concentration of sodium fell from 104.7 to 80.2 mEq/liter ($P > 0.01$). The proportion of water in the ileostomy fluid rose from 90.9 to 94.2% ($P > 0.001$) during this period. When the patients consumed an additional 2 liters of water with the elemental diet, the only significant change observed was a rise in the daily urinary output. The results indicate that under controlled conditions, maintenance on an elemental diet leads to decreases in the gastrointestinal output of fluid, sodium, and potassium, and increases in the water content. These changes were, however, less pronounced than previous reports would suggest.

4710 HERNIATION OF MUCOSAL EPITHELIUM INTO THE SUBMUCOSA IN CHRONIC ULCERATIVE COLITIS. *(E.)* Dyson, J. L. (City Hosp., Nottingham, England). *J. Clin. Pathol.* 28(3):189-194, 1975.

The mechanism of glandular herniation on chronic ulcerative colitis and its relation to carcinoma was studied in 27 patients. They had had colitis from 3-24 yr and 8 had one or more carcinomas. All slides from biopsy specimens in each case were examined. Of 27 cases, 11 showed crypts, cysts, or abscess walls of glandular epithelium in the submucosa. This misplaced epithelium occurred in all parts of the colon, either in islands or as downgrowths continuous with the mucosal glands. When surgery was performed during quiescent periods of ulceration, the mucosal downgrowth was seen usually to occur where the muscularis mucosae had been breached and replaced by a lymphoid aggregate. Slight glandular projection into lymphoid aggregates occurred in almost all cases, but projection into the submucosa was relatively rare. Histological widening of the muscularis mucosae occurred in 8 of 11 patients with mucosal herniation and in 6 with no herniation. There was glandular crowding in 9 cases, 5 of which were associated with herniation. The degree of present inflammation or part ulceration did not bear any relation to herniation. None of the patients with carcinoma had ulcerative colitis for less than 8 yr. Two patients had the disease for 14 and 15 yr, but did not develop carcinoma. Herniation and carcinoma developed independently of each other. It is concluded that herniation is probably due to sustained contraction of the muscularis mucosae, and is not in itself an indication os potential malignancy.

4711 IMPORTANCE OF EARLY INTENSIVE TREATMENT IN SEVERE ATTACKS OF ULCERATIVE COLITIS. *(E.)* Barany, F.; Lindholmer, B. (St. Erik's Hosp., Stockholm, Sweden). *Rend. Gastroenterol.* 6(3): 174-178, 1974.

The clinical course in 41 cases of emergency surgery associated with ulcerative colitis is reviewed to determine whether emergency operations in this disease are avoidable. The first symptoms noted by the patient were slight in 12 cases, moderate in 22, and severe in seven. The mean amount of time elapsed between the onset of symptoms and the first visit to a physician was 18.1 days, while the mean duration between first visit to a doctor and diagnosis and emergency surgery averaged 35.1 days. Among the 41 emergency cases, the diagnosis of ulcerative colitis had been made at an earlier attack in 17 cases, while in 24 cases, surgery was required at the first attack. The data suggest that emergency operations in ulcerative colitis are avoidable if: attacks of this disease are treated immediately upon diagnosis; moderate to severe attacks are treated with high doses of corticosteroids, not sulfasalazine and topical steroids; surgery is performed without delay when a few days of intensive corticoid therapy was not followed by definite improvement of the general condition and bowel inflammation; and anticholinergic and ganglion-blocking agents are avoided during active colitis.

PANCREAS

4722 FURTHER EVALUATION OF TOTAL PANCREATECTOMY. *(E.)* Pliam, M. B.; ReMine, W. H. (Mayo Clin., Rochester, Minn.). *Arch. Surg.* 110(5):506-512, 1975.

The results of 28 total pancreatectomies performed from 1969-1973 were compared with those of 37 total pancreatectomies performed from 1942-1969. The entire series of 64 patients included 39 men and 25 women, aged 28-77 yr. Among the 40 patients who underwent total pancreatecomy for cancer, 24 had pancreatic carcinoma, 2 islet cell carcinoma, 9 ampullary carcinoma, 3 cystoadenocarcinoma, 1 duodenal carcinoma, and 1 rhabdomyosarcoma. At 6 months, 1 yr, and 3 yr, the survival for the early series was 78, 50, and 17% resp. For the recent series, corresponding rates were 80, 56, and 44%. While not statistically significant, these differences suggest survival rates may be improving over the early series. The difference in survival of cancer and noncancer patients was significant at 1 yr (53 *versus* 83%) and was more striking at 3 yr (25 *versus* 83%). The longest survival was 29 yr 3 months, after total pancreatecomty for islet cell tumor. The longest survival in patients with adenocarcinoma of the pancreas was 6 yr 8 months; in patients with ampullary carcinoma, 6 yr 6 months; in patients with cystadenocarcinoma, 4 yr 9 months; and patients with duodenal carcinoma, 10 months. Of the 5 patients who underwent total pancreatectomy for chronic pancreatitis, the longest survival was 8 yr. In the recent series, wound infection decreased from 33 to 11%, gastrointestinal tract bleeding from 28 to 15%, subphrenic abscess from 20 to 11%, and dumping syndrome from 14 to 7%. The incidence of diabetic ketoacidosis was only 3% for the entire group and did not differ between the early and recent series. However, the frequency of difficult diabetes in the early postoperative period decreased from 25% in the early series to 15% in the recent series. Recognition of the fact that relatively small doses of insulin are necessary to control diabetes in these patients probably accounts for the improvement in management. Major gastrointestinal tract bleeding decreased from 20% to 0 through the use of more extensive gastric resection. These recent results are more favorable than those reported for a group of comparable patients undergoing standard Whipple procedures for malignant lesion at the same institution.

4723 RELATIONSHIP BETWEEN ALCOHOLISM AND PANCREATIC INSUFFIENCY. *(E.)* DiMagno, E. P.; Malagelada, J. R.; Go, V. L. M. (Mayo Clin., Rochester, Minn.). *Ann. NY Acad. Sci.* 252:200-207, 1975.

Basal pancreastic trypsin and lipase outputs in response to a maximal stimulatory dose of cholecystokinin-pancreozymin (CCK-PZ, 0.25 CHR U/kg/min i.v.) were measured in 17 patients (11 men and 6 women, aged 35-71 yr) with chronic alcoholic pancreatitis and in 21 healthy men (aged 21-56 yr). In the controls, maximal CCK-PZ stimulation produced a 2.84-fold increase in lipase output and a 3.5-fold increase in trypsin output over basal levels. No significant increase above basal enzyme levels occurred in chronic pancreatitis. The ratio of lipase to trypsin output in both the basal and stimulatory state was significantly higher in controls than in chronic pancreatitis patients. All 5 patients with a greater than 20-yr history of alcoholism had lipase and trypsin outputs less than 10% of normal maximal values; of the 12 patients with alcoholism of 10-20 yr duration, 11 had below-normal lipase outputs. All patients with greater than 20 yr of alcoholism had pancreatic calcification, steatorrhea, and diabetes. Although 8 patients with a shorter duration of alcoholism had steatorrhea and 7 had diabetes or steatorrhea, only 4 had all of these. The data suggest that lipase secretion is a more reliable predictor of exocrine secretory reserve function than is trypsin secretion and that steatorrhea is a late but inevitable sequel of a progressive decline of pancreatic exocrine enzyme outputs.

4737 CHRONIC CALCIFYING PANCREATITIS IN BRAZIL: MORPHOLOGICAL STUDIES. *(E.)* Nogueria, C. E. D.; Dani, R.; Brandao, H. S.; Nunes, A. (Fac. Med., Univ. Minas Gerais, Belo Horizonte, Brazil). *Rend. Gastroenterol.* 6(3):157-164, 1974.

A morphological study of 38 cases of chronic calcifying pancreatitis showed that the calcifications were diffuse in 33 patients, localized in the head in 4, and localized in the body and tail in 1. Stenosis of the cephalic segment of the duct was observed in all 21 patients submitted to an operative pancreatography; 4 of these patients had a second stenosis in the body and in the tail. Retention cysts were observed in the pancreas of 9 subjects and pseudocysts in 6. Diffuse and heavy induration was grossly present at operation in the 33 patients with diffuse calcifications. In 3 cases with segmental calcifications the fibrosis was more pronounced in the calcified area but was evident in the whole pancreas; in 2 cases with stones in the head of the pancreas, only light sclerosis was seen in the body and the tail. Two patients showed intense edema of the whole pancreas and 15 presented with severe sclerosis of the peripancreatic tissue. The diameter of the common duct, studied in 33 cases by i.v. cholangiography and/or operative radiomanometry, was 0.5-2.3 cm (mean 1.06 ± 0.08). Diffuse portal hypertension was detected in 3 patients and segmentary portal hypertension due to thrombosis of the splenic vein was observed in 1 case. Enlargement of the head of the pancreas was responsible for duodenal obstruction in 3 cases. Microscopic examination of 5 autopsy cases and 19 surgical specimens showed a high incidence of parenchymal atrophy (65%), regression to the canalicular status (70%), islet atrophy (80%), dilation of the ducts (80%), protein plugs (50%), and fibrosis (83%). In 2 patients carcinoma of the pancreas was found 3 and 5 yr after diagnosis of CCP.

4738 PANCREATICO-JEJUNOSTOMY IN CHRONIC PANCREATITIS. AN APPRAISAL OF 29 CASES. *(E.)* Arnesjo, B.; Ihse, I.; Kugelberg, C.; Tylen, U. (Dep. Surg., Univ. Lund, Sweden). *Acta Chir. Scand.* 141: 139-148, 1975.

Pancreatico-jejunostomy (end-to-side after resection of the pancreatic tail or side-to-side following longitudinal cleaving of the pancreatic duct) was performed on 29 patients (22 men and 7 women, aged 14-61 yr) with chronic relapsing or acute relapsing pancreatitis. A follow-up study ranging from 6 months to 10 yr is presented. The patients were allotted to 3 groups according to the severity and extent of the inflammatory involvement at operation. The diagnostic findings obtained at the preoperative evaluation correlated well with these groups. In some patients, however, the inflammatory process was mainly confined to the ductal system, as revealed by pancreatography, while in others the changes were most marked in the parenchyma, as found at histologic examination. Twenty-one caudal pancreatico-jejunostomies and 8 longitudinal anastomoses were performed. Overall results were excellent in 20 patients, good in 6, fair in 3, and poor in none. The rate of postoperative complications was low: no mortality, 1 spontaneously healed anastomosis insufficiency, 2 cases of subphrenic abscess, and 5 cases of postoperative diabetes. Only one patient had a recurrent attack of acute pancreatitis postoperatively. Reanastomosis was successfully performed. It is concluded that pancreatico-jejunosotomy, based on findings at pancreatography, may reduce the risk of serious, late complications of the disease.

4739 EVALUATION OF PROPHYLACTIC ANTIBIOTICS IN ACUTE PANCREATITIS. *(E.)* Howes, R.; Zuidema, G. D.; Cameron, J. L. (John Hopkins Med. Inst., Baltimore, Maryland). *J. Surg. Res.* 18(2):197-200, 1975.

A prospective randomized study was performed to compare the incidence of septic complications in patients with acute pancreatitis treated with antibiotics and in patients receiving no antibiotic therapy. Of 48 patients randomized to the antibiotic group, 44 received ampicillin (1 g every 6 hr for 5 days) and 4 received lincomycin (600 mg i.v. every 8 hr followed by 500 mg p.o. every 6 hr for 5 days). Forty-seven patients received no antibiotic therapy. Age, race, sex distributions were similar within the 2 groups, and in each group alcohol consumption was the most common etiology of the pancreatitis. Average initial serum amylase values were 392 Caraway U/100 ml in the antibiotic group and 365 Caraway U in the no antibiotic group. The amylase level remained elevated for an average of 2 days in both groups. Five septic complications developed in the antibiotic group, and 6 in the untreated group. In the antibiotic group 3 patients developed pneumonia and 2 developed pancreatic abscess. An organism was grown in only 2 of these 5 cases and was an ampicillin-resistant Klebsiella. In the no antibiotic group there were 4 pneumococcal pneumonias, all sensitive to ampicillin, and 1 pancreatic abscess secondary to ampicillin-resistant Klebsiella and Enterobacter. One patient given no antibiotics developed a septicemia, but its source was not found. One patient in the antibiotic group developed an ampicillin allergy and was switched to lincomycin. The overall incidence of septic complications in the two groups did not differ significantly. These results show no advantage of using antibiotics in the treatment of acute pancreatitis until there is clinical or bacteriological evidence of sepsis.

4740 CONSISTENT PROTECTION FROM PANCREATITIS IN CANINE PANCREAS ALLOGRAFTS TREATED WITH 5-FLUOROURACIL. *(E.)* Castellanos, J.; Manifacio, G; Toledo-Pereyra, L. H.; Shatney, C. H.; Lillehei, R. C. (Dep. Surg., Univ. Minnesota, Minneapolis). *J. Surg. Res.* 18(36):305-311, 1975.

The ability of 5-fluorouracil (5-FU) to protect against pancreatitis following pancreas transplantation was studied in 5 groups of adult mongrel dogs. A no-transplant control group (10 dogs) was treated with azathioprine (5.0 mg/kg/day i.v. for 3 days, then 2.5 mg/kg/day p.o) plus 5-FU (15 mg/kg/day i.v. on day 1, then 7.5 mg/kg/day p.o. for 1 week). Control transplanted dogs (6) received no immunosuppressive treatment. Seven transplanted dogs were given azathioprine only; 8 of 14 recipient dogs treated with both azathioprine and 5-FU (15 mg/kg/day the day of the transplant and then 7.5 mg/kg/day for 1 week) received a pancreas from donors treated with 5-FU (15 mg/kg/day) for 2 days and 1 hr before surgery, while the remaining dogs received a pancreas from a donor treated with 5-FU only 1 hr before surgery. Dogs that received no immunsuppression lived an average of 5.5 days. When azathioprine was added to the treatment, survival increased to an average 11.1 days. Only when 5-FU was added to the minimal immunosuppression treatment did the transplanted dogs live for periods up to 4 weeks. Results were best in dogs receiving a pancreas from donors given 5-FU for 2 days before transplantation. The 4 recipient groups did not differ with respect to postoperative total protein, albumin, or blood glucose levels. The postoperative total leukocyte count of untreated recipients was higher than that of the other groups, but the difference was significant only on the 3rd and 4th posttransplant days. Animals treated with azathioprine 8 and 5-FU had significantly lower amylase concentration throughout the posttransplant period, and serum amylase values correlated well with the preservation of the normal architecture of the pancreatic tissue after transplantation. Pancreatitis and peritonitis were present in more than 1/2 the dogs treated with azathioprine alone, whereas there was no case of pancreatitis and a decreased incidence of peritonitis in animals given azathioprine plus 5-FU.

4741 PHOSPHOLIPASE A ACTIVITY IN EFFUSIONS FROM PATIENTS WITH ACUTE PANCREATITIS. *(Fr.)* Thouvenot, J. P.; Durand, S.; Douste-Blazy, L. (Purpan Hosp., Toulouse, France). *Arch. Fr. Mal. App. Dig.* 63(6):479-483, 1974.

By measuring the amount of ^{32}P-phosphatidyl ethanolamine hydrolyzed in the presence of sodium deoxycholate and the absence of trypsin, phospholipase A activities were determined in ascites fluid from five patients with acute pancreatitis and from seven patients with alcoholic cirrhosis and no evidence of pancreatic damage. Results are expressed in nM of ^{32}P-lysophosphatidyl ethanolamine (LPE) liberated by 1 ml of ascites fluid. After 5 min incubation, LPE values ranged from 70 to 815 nmol/ml (mean 330 nmol/ml) in fluid from patients with pancreatitis. The variation in these results is probably due to differences in the severity of the pancreatic lesion and the distance between the foci of inflammation and the peritoneum and does not appear to be caused by enzyme inactivation during the determination or by activation of prophospholipase in the ascites fluid. In two patients, plasma phospholipase activities were lower than those in ascites fluid, suggesting that the enzyme does not originate in the circulatory system. Phospholipase A activities ranged from 25 to 159 nM LPE/ml/5 min (mean 58 nM/ml/5 min) in ascites fluid from cirrhotics). Individual variations in phospholipase A activities in cirrhotics might be due to the chronicity of effusion and absorption of fluid. Student's test demonstrated that for every incubation time employed (5-60 min), phospholipase A activities were significantly higher in ascites fluid from patients with acute pancreatitis than in that from cirrhotics. No lysophospholipase activity was detected in either group.

4742 EPIDEMIOLOGY AND AETIOLOGY OF CHRONIC CALCIFYING PANCREATITIS IN BELO HORIZONTE, BRAZIL. *(E.)* Dani, R.; Nogueira, C. E. D.; Furtado, M.; Leal, S. (Sch. Med., Fed. Univ. Minas Gerais, Belo Horizonte, Brazil). *Rend. Gastroenterol.* 6(3):153-156, 1974.

To determine the frequency and etiology of chronic calcifying pancreatitis (CCP) in Brazil, data from autopsy records and personal cases were compared with findings in healthy controls matched for race, sex, profession, and age. Among 6060 autopsies, diseases of the digestive system were the cause of death in 1205 cases. Of the latter, 256 cases showed pancreatic involvement which was diagnosed as chronic pancreatitis in 13. Thus, the disease occurred in 0.21% of the total cases and in 1.07% of diseases of the digestive system. Of 54 personal cases, 43 (41 men and 2 women) were alcoholic. The difference in age at onset of symptoms between this group and the 11 nonalcoholics (6 women and 5 men) was significant. Moreover, 54.5% of persons with CCP of unknown etiology were aged 6-25 yr, whereas only 1 alcoholic was under 25 yr. Comparison of dietary intake of 27 CCP patients and matched controls revealed that alcohol consumption and carbohydrate and calorie intake were significantly higher in patients than in controls. Protein intake (mainly vegetable proteins) was also significantly higher in the patients. These results do not support the possibility of protein deficiency being a cause of pancreatitis.

4743 CHANGES DUE TO PANCREATIC CYSTS SEEN ON RETROGRADE ENDOSCOPIC CHOLEDOCHO-PANCREATICOGRAMS. *(Ger.)* St. Stender, H.; Seifert, E.; Misaki, E.; Luska, G.; Lesch, P. (Med. Coll., Hannover, Germany). *Fortschr. Gen. Rontgenstr. Nuklearmed.* 120(3):253-258, 1974.

Endoscopic choledocho-pancreaticography (ERCP) was evaluated in the diagnosis of pancreatic disease. This method not only revealed changes in the pancreatic duct due to chronic inflammations and tumors but also demonstrated cysts directly or resultant secondary changes in the pancreatic and bile ducts. Among 612 ERCP's, 10 patients were found with pancreatic cysts. The following signs were characteristic: the cyst may be filled from the pancreatic duct; round void spaces in the contrast agent fillings showing the peripheral ducts and the parenchyma may be due to cysts; the pancreatic duct may be abruptly occluded or be of the tapering type; narrowing or displacement of the intrapancreatic portion of the common bile duct may result from cysts. Distinction between benign and malignant cystic changes in the pancreas is difficult. Following ERCP the patient must be observed carefully for complications due to possible activation of inflammatory processes.

4744 OBSERVATIONS ON ACUTE PANCREATITIS: A POSTMORTEM REVIEW. *(E.)* Gillespie, W. J. (R. Infirm. Edinburgh, Scotland). *J. R. Coll. Surg. Edinb.* 20(1):36-41, 1975.

Postmortem findings in 126 cases of acute pancreatitis (47 men and 79 women) revealed 53 cases of gallstones compared to an expected incidence of 29.95. The stones were in the gallbladder only in 30 cases, in the common bile duct in 16, and were obstructing the ampulla of Vater in 7. Pancreatic abscesses occurred in 14 patients and pseudocysts in 9; fat necrosis was visible to the naked eye in 108 cases. The association between acute pancreatitis and gallstone disease was highly significant and is hypothesized to be the result of the high incidence of gram-negative bacteria associated with cholelithiasis. The frequently focal nature of the pancreatitis is also compatible with an infective origin; in this series, for example, the site of pancreatic disease was in the head alone in 27 cases including 10 subjects with gallstones. Only 3 patients had a history of alcoholism. Despite the increasing accuracy of diagnosis, failure of diagnosis still occurs in acute pancreatitis. The majority of patients are elderly or have multiple preexisting disorders.

4745 MORPHOMETRIC-STATISTICAL ANALYSIS OF PANCREATIC ARTERIES IN CHRONIC PANCREATITIS. *(Ger.)* Kaiser, G.; Hommel, G. (Inst. Pathol., Univ. Erlangen-Nuremberg, Erlangen, Germany). *Virchows Arch.* [*Pathol. Anat.*] 365(2):103-118, 1975.

Changes in pancreatic vessels in chronic pancreatitis and whether the diameter of the arterial vessels is reduced, are statistically examined. Histological preparations from two groups, treated with the van Gieson stain, were used for the investigation: Group I consisted of 50 subjects with healthy pancreatic tissue, and group II of 50 operative cases of chronic pancreatitis. At a 320-fold magnification, media thickness, vessel diameter, and intima thickness of four arterial vessels in each case were determined by a measuring scale in the lens of a light microscope. The test results were transferred to perforated cards and analyzed by computer. Arterial vessels in the endothelium in case of pancreatitis showed cell nuclei projecting into the lumen. Especially remarkable was the thickening of the subendothelial intima tissue in the form in intima-fibrosis and intima-elastosis; atrophy of the media was noted in later stages. The lumen of the arterial vessels seemed to be considerably constricted as compared to that of the venous vessels. The relations between media thickness and vessel radius in both groups were determined and, using regression lines as a model, vessel constriction was found to be statistically significant. Although regression lines for the corresponding thickness were quite close, they were still significantly different. This remaining difference could have been caused by alteration in the media or also by additional influential characteristics that differ in the two test groups. The relation between vessel radius and media thickness was examined with regard to the following variables: distribution of age, sex, and phases of parenchyma reduction. Results show that the differences between the two groups were hardly influenced by age. The different distribution of sex seems to weaken the results more than to intensify it. Finally, the phase of parenchyma reduction corresponds to the extent of vessel alteration. These vessel alterations probably represent an adaption of the reduced parenchyma to the lowered demand for blood. On the other hand, it is rather unlikely that such alteration is an important pathogenetic factor of chronic pancreatitis or a consequence of exterior pressure caused by perifocal inflammation and incisive cicatricial tissue.

LIVER AND BILIARY TRACT

4780 POST-JEJUNOILEAL-BYPASS HEPATIC DISEASE. ITS SIMILARITY TO ALCOHOLIC HEPATIC DISEASE. *(E.)* Peters, R. L.; Gay, T.; Reynolds, T. B. (Univ. South. Calif. Sch. Med., Los Angeles). *Am. J. Clin. Pathol.* 63(3):318-331, 1975.

Liver structural changes were followed by serial hepatic biopsies in five patients with hepatic disease following jejunal-bypass for extreme obesity. Three patients were nonalcoholics while two decreased their intake following surgery. Hepatic dysfunction became manifest 2.5-5 months after bypass when weight losses ranged from 65-127 lb. Nausea and vomiting, abdominal pain and hepatomegaly were present in all five while ascites and splenomegaly were detected in three. Laboratory findings, which included hyperbilirubinemia, decreased albumin, prolonged prothrombin time, moderate elevation of alkaline phosphatase and transaminases with the rise in SGOT greater than SGPT, were identical to those seen in acute alcoholic hepatic disease. Hepatic microscopic changes included centrilobular or focal alcoholic hyalin deposition, intrasinusoidal collagenosis, fatty degeneration and neutrophilic infiltration. Four of the five patients died in hepatic failure despite hyperalimentation and re-establishment of intestinal continuity. It is concluded that further study of the mechanism of post-bypass hepatic disease may help in understanding the pathogenesis of alcoholic liver disease.

4781 ARTERIAL INFUSION CHEMOTHERAPY OF HEPATOMA.

(E.) Cady, B.; Oberfield, R. A. (Lahey Clin., Boston, Mass.). *Lahey Clin. Found Bull.* 24 (2):49-55, 1975.

Regional arterial infusion chemotherapy for carcinoma of the liver was used in 18 of 54 patients. Of the remainder, five underwent resection, and the rest, untreated, served as non-concurrent controls. Tumors were graded as well-, moderately-, or poorly differentiated; 17 tumors were classified as liver cell carcinomas and one was classified as cholangiolar. Infusion catheters placed after exploration revealed that the extent of the disease precluded curative hepatic lobectomy. 5-Fluorodeoxyuridine was given in daily doses of 0.3 mg/kg. Occasionally, fluorouracil was used instead, at 3-5 mg/kg/day. Methotrexate was used in one patient (5 mg/kg/day). Treatment was continued as long as catheter and arterial patency could be demonstrated angiographically. Of the 18 patients given infusion, five died as a result. Of these, two died from fibrinolysin production with hemorrhage and pneumonia; one from hemorrhage of esophageal varices, and one from subphrenic abscess and pneumonia, all in the first yr of the program. In the last 5 yr, there was only one treatment related to death. Of 11 males (18-68 yr), median survival rate after elimination of three treatment-related deaths was 16.5 months. Of seven females (12-69 yr), median survival time after elimination of two treatment related deaths was 8 months. Excepting four patients who had no postoperative follow-up, median hepatic arterial patency time was 8.5 weeks. Of 18 patients, 11 were definitely improved, and eight were substantially improved, symptomatically. During the last 5 yr, 10 of 12 were improved, and eight of 12 were substantially improved. Symptomatic improvement was accompanied by a 16.5 month increase in median survival time. Between 1957 and 1962, two patients had resection and 21 no treatment; one survived over 1 yr. Between 1962 and 1965, six patients were given infusion and six no treatment; one survived over six months. After 1966, 12 patients were given infusion, three had resection, and eight had no treatment; 11 survived 6 months, and seven over 1 yr. The difference in survival time between patients not undergoing resection before 1962 and after 1966 is significant. No patient on infusion had all laboratory or clinical features return to normal. It is concluded that hepatic carcinoma may be substantially improved by infusion chemotherapy if resection is not possible.

4782 KINETICS OF RADIOCOPPER IN WILSON'S DISEASE.

(Ger.) Willvonseder, R.; Goldstein, N. P.; Tauxe, W. N. (Mayo Clin. Mayo Found., Rochester, Minn.). *Wien. Z. Inn. Med.* 54(5/6):226-233, 1973.

Plasma incorporation, liver uptake, urinary and fecal excretion, and body retention of i.v. administered ^{64}Cu and ^{67}Cu were examined in 35 homozygous and heterozygous carriers of Wilson's disease, and in a normal control group. Plasma incorporation in heterozygous patients was lower than in normal subjects, and there was practically no incorporation at all in homozygous patients with manifest Wilson's disease. The liver uptake was slightly higher in heterozygous patients than in normal subjects, but it showed steady increase in homozygous patients, and reached extremely high values in the preclinical stages of Wilson's disease. The urinary and fecal excretion was lower in heterozygous patients than in the control group, and the lowest values were found in preclinical stages. The urinary excretion was higher in untreated homozygous patients with manifest Wilson's disease than in heterozygous patients and in the control group, while the fecal excretion was practically zero in the former group. The mean biological half-life period of ^{64}Cu was determined to be 17 days in the control group, 39.4 days in heterozygous patients, and 97 days in homozygous untreated patients. The results indicate that copper is not bound to ceruloplasmin in patients with Wilson's disease. The liver copper uptake mechanism is still compensated in preclinical stages, but it is decompensated in clinical stages of Wilson's disease. Due to their high discriminatory efficiency, radiocopper investigations are recommended in all patients suspected of an error in copper metabolism.

4783 PRIMARY ANGIOSARCOMA OF THE LIVER. REVIEW ARTICLE.

(E.) Alrenga, D. P. (Hektoen Inst. Med. Res., Chicago, Ill.). *Int. Surg.* 60(4): 198-203, 1975.

The characteristics of primary angiosarcoma of the liver are reviewed for both the adult and infantile forms. The disease formed 1.8% of all primary liver cancers in a review of the literature between 1954 and 1974, and had an autopsy incidence of 6/100,000. There was no geographic variation in incidence. The most common etiologic agent was thorium dioxide, responsible for at least 50 cases since 1947. Angiosarcoma comprised over 1/3 of all thorium dioxide-induced malignancies: eight cases of angiosarcoma in 28 cases of postnecrotic necrosis induced by arsenic trioxide; one caused by γ-radiation from a radium needle lodged in the heart; and one in a patient treated for 17 yr with arsenic for psoriasis. There were about 20 deaths attributed to vinyl chloride-induced angiosarcoma. Clinically, 15% of the patients were under 40 yr of age, and males predominated 2:1 over females. The commonest symptoms were rapid hepatic enlargement with epigastric pain, ascites (often hemorrhagic), and jaundice, although the mode of presentation was quite variable in general. Infantile hemangioendothelioma occurred in children under 4 yr of age; 70% were diagnosed before 6 months of age. Hepatomegaly was the only consistent finding on physical examination. Abdominal distension, vomiting, diarrhea, or constipation were the most common symptoms. Gross morphology of both angiosarcoma and infantile hemangiendothelioma were very similar. Tumors were solitary, multicentric, or diffuse, and varied from fleshy nodular masses to large blood filled cycts. Histopathologically, angiosarcoma, as opposed to the infantile form, had more nuclear atypia, mitotic activity, and giant cell formation. The most distinguishing feature was the presence of intercommunicating spaces lined by atypical endothelial cells confined within a thin reticulin network. Unique microscopic features also included neoplastic cells simulating Kupffer cells, extramedullary hemopoeisis within the tumor's vascular spaces, and ability of the tumor cells to ingest hemosiderin. The histologic pattern of the infantile form showed either vascular spaces lined by plump endothelial cells and separated by collagenous and myxoid stroma, or poorly formed vascular spaces with large pleomorphic endothelial cells and extramedullary hemopoeisis. Adult angiosarcoma was commonly associated with fibrosis or cirrhosis and the infantile forms with cutaneous hemangioma. Angiosarcoma had an unfavorable prognosis, while the infantile form had a more favorable one, with a 50% survival rate.

4784 EXCHANGE TRANSFUSION FOR REYE'S SYNDROME.

(E.) Lewis, J. D.; Varma, R. R.; Harrington, G.; Caspar, J.; Ackamnn, J. J.; Darin, J. C. (Med. Coll. Wisconsin, Milwaukee). *J. Surg. Res.* 18(3):327-329, 1975.

Patients with Reye's syndrome, all in grade IV-V coma, were treated by exchange transfusion. Blood components were used for more efficient use of resources. Packed blood cells were washed with saline and combined with fresh-frozen citrate-phosphate-dextrose plasma. Cerebral edema was treated by administration of dexamethasone and mannitol, and the colon was "sterilized" with neomycin p.o. and *via* enema and fructose *via* enema. A total of 21 exchanges were performed on the nine patients. One patient responsed rapidly to one exchange. Six required two exchanges; five of these responded. Two required four exchanges before response. One patient was given peritoneal dialysis. Computerization of EEG activity showed significant diminution of delta activity with associated increase in theta and alpha activity in those treated by exchange transfusion, but not in the patient undergoing dialysis, until exchange transfusion had reversed the clinical course. It is concluded that exchange transfusion is extremely effective in the treatment of profound Reye's syndrome.

4785 'PURE' HEPATIC FORMS OF WILSON'S DISEASE IN CHILDREN: TEN OBSERVATIONS.

(Fr.) Odievre, M.; Vedrenne, J.; Landrieu, P.; Alagille, D. (Parrot Hosp., Bicetre, France). *Arch. Fr. Pediatr.* 31(2/3):215-222, 1974.

Observations of 10 cases of Wilson's disease in children are presented. In all cases, the involvement was predominantly or exclusively hepatic and included cirrhosis (nine cases), intrahepatic portal hypertension (three), chronic active hepatitis (nine), and acute anemia and hepatocytic insufficiency due to acute transitory hemolysis (five cases, fatal in four). In one case, Wilson's disease was diagnosed by systematic examination following the deaths of two siblings from acute hemolysis and hepatocytic insufficiency caused by Wilson's disease. The clinical and biological polymorphism of Wilson's disease makes diagnosis difficult. The authors suggest that certain features of hepatic involvement are indicative of a metabolic origin: parallel decrease in the different factors of the prothrombic complex; coexistence of hepatic symptoms with signs of renal tubular involvement; association of hepatic portal fibrosis with steatosis; hepatic cytolysis; and normal levels of α_2-globulins associated with other hepatic symptoms. Definitive diagnosis is demonstrated by ceruloplasmin concentration below 200 mg/liter, plasma copper concentration below 60 µg/100 ml, and cupruria greater than 100 µg/24 hr. It is concluded that an elevated concentration of hepatic copper resolves diagnosis in doubtful cases.

4786 SPECTRUM OF LIVER DISEASE IN RENAL TRANSPLANT RECIPIENTS.

(E.) Ware, A. J.; Luby, J. P.; Eigenbrodt, E. H.; Long, D. L.; Hull, A. R. (Univ. Texas Southwest. Med. Sch., Dallas, Texas). *Gastroenterology* 68(4):755-764, 1975.

Renal transplant patients over a 4 yr period were reviewed with an attempt to define episodes of liver disease in these patients in terms of their nature, etiology and prognosis. There were 82 patients at risk in development of liver disease. They were observed for 6 months to 4 yr, during which time they were frequently assessed for hepatic dysfunction clinically and by laboratory tests including serum bilirubin, serum alkaline phosphatase, and SGOT. Determination of the hepatitis B surface antigen (HB_sAg) were performed monthly, and at least one serum sample from each patient was assayed by solid phase radioimmunoassay, and cytomegalovirus (CMV) antibody was assayed by complement fixation. CMV was also assayed by innoculation of cultured cells with samples of urine or homogenized liver. The minimum criteria for liver disease were two consecutive elevated SGOT levels, 1 week apart. Of the 82 patients, 31 (38%) developed evidence of liver disease after the transplant. Of these, eight cases were acute, self limited, reversible, and benign; two were acute, and fatal hepatitis, and 21 were a form of chronic disease with cirrhotic potential. The development of the disease was not influenced by age, sex, nature of the kidney disorder, source of donor, quality of HLA tissue match, or the dosage of azathioprine and steroid therapy given to all patients. Of the 31 cases, 25 began within 6 months of transplantation. The eight cases of reversible disease lasted from 1-20 weeks. A biopsy performed in one case showed multiple fresh granulomata. Typical CMV inclusions were found in enlarged and degenerating hepatocytes. HB Ag was not present in any case. In six of the cases, there was seroconversion to CMV within a few weeks of the disease's onset, and CMV was found in the urine in three cases. Of the two patients with acute fatal disease, one was HB$_s$Ag positive. The other was negative, but CMV seroconversion coincided with the onset of the illness. Of the 21 patients with chronic disease, 16 underwent seroconversion to CMV. Follow-ups of from 6-40 months showed constant liver function test results. In three patients, there were five episodes of acute reversible icterus, probably etiologically unrelated. Three of the 21 patients had persistent HB$_s$Ag antigenimia. One of these, however, was positive for HB$_s$Ag for 2 1/2 yr before any abnormality of liver function was detected. It is suggested that CMV was a likely cause for a majority of the cases, while hepatitis B may have been implicated in a few, but the results are not conclusive.

4787 INVESTIGATION OF THE HEPATIC CATALASE ACTIVITY IN PATIENTS WITH MALIGNANT TUMORS AND FATTY LIVER. *(Ger.)* Guelzow, M.; Falkenhagen, D.; Huetter, J.; Arendt, R.; Teichmann, W. (Fac. Med., Univ. Rostock, Germany). *Z. Inn. Med.* 29(23): 959-964, 1974.

The liver catalase activity was determined by manometry in biopsy specimens from 32 normal subjects, 31 patients with malignant tumors of different localizations, and in 25 patients with fatty liver to establish the relation between the catalase activity and the pathological state. The liver catalase activity was highest with 13.29 IU/mg in normal subjects, and significantly lower in tumor patients, and especially in patients with moderate and serious fatty liver. The catalase activity was lowest in patients with serious degree of fatty liver, being significantly lower than in patients with moderate degree of fatty liver. The catalase activity, while not age-dependent, was highest in the 51-70 yr age group. No significant sex-conditioned difference was established. The difference between tumor patients with and without metastases was insignificant.

4788 HEPATIC ARTERY LIGATION AND CYTOTOXIC INFUSION IN TREATMENT OF LIVER NEOPLASMS. *(E.)* Zike, W. L.; Safaie-Shirazi, S.; Gulesserian, H. P. (Univ. Iowa Hosp., Iowa City). *Arch. Surg.* 110(5):641-643, 1975.

Hepatic artery ligation with distal infusion of the artery with cytotoxic drugs was used to treat 38 patients with primary or secondary hepatic neoplasms. None showed evidence of major extrahepatic metastases. Laparotomy was performed, the primary tumor was resected whenever possible, and the hepatic artery ligated distal to its extrahepatic branches. A catheter was inserted distal to the ligation and was ligated to the artery at two or more sites. The lesser omentum, falciform ligament, and triangular ligament were transected and the gallbladder removeed. The catheter was kept open by constant infusion of saline and heparin solution, and when liver enzymes returned to preoperative levels, patients were infused with 12 mg/kg/day fluorouracil in heparinized saline. Treatment was discontinued when the catheter became displaced, became clogged by clotting, or when drug toxicity appeared. The average fluorouracil infusion lasted 45 days. The median survival time was 13.3 months; the longest survival was up to 44 months. Of the eight surviving patients, median survival time was 17 months. The primary tumor was in the large bowel in 25 patients, and in the liver in five. Of the 38, three had ligation only, with no infusion. There were marked postoperative elevations in alkaline phosphatase, SGOT, and LDH. Values returned to normal within 8 days. It is concluded that this method does not destroy the entire tumor, but does result in substantial palliation with minimal morbidity and mortality.

4789 THE DIAGNOSIS OF JAUNDICE BY THE MINI-LAPAROTOMY OPEN TRANSHEPATIC CHOLANGIOGRAM. *(E.)* Stein, H. D. (Lincoln Hosp., Bronx, N.Y.). *Ann. Surg.* 181(4):386-389, 1975.

Diagnosis of the etiology of obstructive jaundice was made by open transhepatic cholangiography (minilaparotomy) in 23 patients. Routine diagnostic procedures had failed in all. Five had ascites and four had elevated prothrombin levels. The liver was visualized through a 4 cm subxiphoid incision using local anesthesia. The catheter was inserted and contrast material injected into a bile duct under fluoroscopic control. Cholangiograms were attempted in all cases. Liver biopsies and cultures of bile and ascitic fluid were obtained when necessary. The procedure resulted in successful diagnosis in 21 of the 23 patients. In one unsuccessful case the cholangiogram was unsuccessful and surgery resulted in a diagnosis of intrahepatic cholestasis secondary to Gold therapy. In the other case, cholangiography showed obstruction of the common hepatic duct, but surgery disclosed carcinoma of the pancreas. Cholangiography was unsuccessful in two other patients in whom the procedure was attempted only perfunctorily because diagnosis was already evident by direct observation and biopsy. Of eight patients in whom non-surgical disease was diagnosed or diagnosis was in question, five had cholelithiasis. In the other three, precise diagnosis was changed but therapy was not. In 14 cases with high probability of surgical disease, three were saved surgery and clinical diagnosis was proved incorrect in four. There were no wound complications, bile leaks or hemorrhage, and future surgery was not interfered with in any patient. It is concluded that minilaparotomy is safe and reliable, and has a nearly 100% accuracy, low complication rate, and minimal limitations of use.

4790 HEPATIC CELL ADENOMAS, SPONTANEOUS LIVER RUPTURE, AND ORAL CONTRACEPTIVES. *(E.)* Ameriks, J. A.; Thompson, N. W.; Frey, C. F.; Appelman, H. D.; Walter, J. F. (Univ. Michigan Med. Cent., Ann Arbor). *Arch. Surg.* 110(5):548-557, 1975.

The clinical and pathological features of hepatic cell adenoma were studied in eight patients. All were women, aged 25-44 yr; all had been taking oral contaceptives containing a progestogen and estrogen combination, from 6 months to 9 yr, and all but one had been at least twice pregnant before starting the drug. Average tumor size was 15 cm in diameter, but in three cases where the tumors ruptured, they were 18 cm in diameter. There was no correlation found between tumor size, clinical presentation, age, or duration of drug use. The three patients with ruptured tumors were treated by anatomical right lobectomy, and despite complications in each case, all survived and were followed up for 8 months to 3 yr. Two patients had expanding neoplasms which were excised with a rim of normal tissue. Both recovered with no significant morbidity. Three patients had asymptomatic neoplasms. Two of these were treated by excision with a rim of normal tissue, while the third was given an anatomical right lobectomy. All were well at follow-ups of 5 months, 3 yr, and 5 yr. All tumors consisted of well differentiated hepatocytes organized into sheets and cords, but without lobules, and were partly encapsulated by an incomplete fibrous membrane. It is suggested that there may be a relation between these tumors and oral contraceptives.

4791 LIVER IMPAIRMENT DURING CHRONIC HEMODIALYSIS AND AFTER RENAL TRANSPLANTATION.

(E.) Nielsen, V.; Clausen, E.; Ranek, L. (Rigshosp., Copenhagen, Dnemark). *Acta Med. Scand.* 197(3):229-234, 1975.

The possible causes of aminotransferase elevation were elevated in patients treated with chronic hemodialysis and renal transplantation. Patients were treated with hemodialysis alone (23), hemodialysis and renal transplantation (37), or allotransplantation alone (19). Of the last, 12 had had previous hemodialysis treatment. Tests of serum alanine aminotransferase, prothrombin-proconvertin, and serum protein electrophoresis were done at least four times/month. Clinically, biochemically, and histologically, the patients were divided into five groups: 1) no clinical or biochemical evidence of liver disease; 2) elevated alanine aminotransferases, but no clinical evidence of disease; 3) anicteric hepatitis; 4) icteric hepatitis; and 5) elevated alanine aminotransferases possibly not due to viral hepatitis. Of the 60 patients given hemodialysis, 29 showed no liver disease, nine had transferase elevation, five had anicteric hepatitis, and 10 had icteric hepatitis. A final group consisted of seven patients in whom elevated alanine aminotransferase values were assumed to be due to bacterial sepsis in two, crush syndrome with anuria in two, iron contamination of dialysis water in one, cardiac arrest in one, and severe hemosiderosis of the liver in one. There was no significant rise in cytomegalovirus (CMV) titers in any. Of the 56 patients given renal allotransplants, 28 showed no liver impairment, nine had asymptomatic transferase elevation, 10 had anicteric hepatitis and four had icteric hepatitis. A final group consisted of five patients in whom elevated transferase values were assumed to be due to polycystic kidneys and liver cysts in one, urinary leakage and urinary tract infection in three, and hemosiderosis of the liver in one. CMV titers did not rise significantly in any. In all, 50% of the hemodialysis patients and 50% of the renal transplant patients had elevated transferase levels for longer or shorter periods, while the mortality from hepatitis was 13%. It is concluded that alanine aminotransferase elevation is not a contraindication for performing renal transplant.

4792 INFECTIOUS HEPATIC GRANULOMATOSIS: CLINICAL ASPECTS AND LIVER FUNCTION TESTS.

(Sp.) Hernandez Guio, C.; Rey, R.; Aguirre, M.; Dominguez, A.; Patino, J. (Jimenez Diaz Found., Madrid, Spain). *Rev. Clin. Esp.* 133(1):39-44, 1974.

Of 33 patients with hepatic granulomatosis associated with infectious disease, 12 had tuberculosis, six brucellosis, and 15 leprosy. In four patients with tuberculosis, the liver was the only organ involved; cirrhosis was present in three patients with tuberculosis. Specific granulomatous lesions were found in all 28 patients from whom liver biopsies were taken. In general, symptoms were suggestive of granulomatous hepatitis. Fevers were present in all 12 patients with tuberculosis, in five of those with brucellosis, and in one with leprosy; seven other patients with leprosy ran fevers intermittently. Jaundice was present in seven of those with tuberculosis, in one with brucellosis and, intermittently, in seven with leprosy. Hepatomegaly was observed in 10 patients with tuberculosis, six with brucellosis, and 13 with leprosy. Splenomegaly was present in half of those with leprosy and tuberculosis and in four with brucellosis. Of the liver function tests performed, serum protein fractions exhibited the greatest changes in all three groups of patients. The most specific changes were noted in leprosy, probably as a result of immunological disorders. Turbidity tests were positive, but are considered nonspecific. SGOT values were pathological in four patients with tuberculosis and three with leprosy, suggesting the presence of parenchymal damage. However, none of these patients had histological evidence of cirrhosis. Serum alkaline phosphatase and BSP retention values are considered useful indicators of liver function in afebrile and nonjaundiced patients, resp. However, liver biopsies were the most valuable diagnostic tool. Although leprosy had been diagnosed in 14 patients before liver biopsies were taken, the etiology of hepatic granulomatosis was established only by liver biopsy in almost half of these patients.

4793 THE EFFECTS OF AGE AND LIVER DISEASE ON THE DISPOSITION AND ELIMINATION OF DIAZEPAM IN ADULT MAN.

(E.) Klotz, U.; Avant, G. R.; Hoyumpa, A.; Schenker, S.; Wilkinson, G. R. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *J. Clin. Invest.* 55(2):347-359, 1975.

The disposition and elimination of diazepam were studied in 21 patients with liver disease and in 33 healthy adults aged 15-82 yr. In healthy subjects, plasma diazepam concentration, as determined by gas chromatography, declined biexponentially with a clearance value of 20-32 ml/min following p.o. (10 mg) or i.v. (0.1 mg/kg) administration. Although clearance was not age-dependent, analysis of the i.v. data according to a two-compartment open model indicated that both the initial distribution space and the steady state volume distribution of diazepam increased linearly with age. The increase in the steady state volume distribution was secondary to a change in the initial distribution space. Plasma half-life of desmethyldiazepam, the metabolite of diazepam, showed a similar age dependence although its peak concentration was lower and occurred later than the precursor. Both compounds bound extensively (97%) to plasma proteins. Patients with cirrhosis had a two-fold longer diazepan half-life (105.6 hr) than age-matched controls (46.6 hr) due primarily to similar decrease in total plasma clearance. Appearance of plasma desmethyldiazepam was delayed 3-8 hr compared to controls. Plasma diazepam clearance was also prolonged about two-fold in patients with acute viral and chronic active hepatitis. In cirrhotic and viral hepatitic patients, no correlation was found between plasma half-life or clearance and any of the routine liver function tests. It is concluded that: 1) diazepam plasma concentrations will not accumulate to a greater extent in older than in younger patients, thus making dosage modifications unnecessary; and 2) reduced drug clearance dictates the use of caution in prescribing diazepam to patients with acute or chronic liver disease.

4794 A STAGING SYSTEM FOR HEPATOCELLULAR CARCINOMA: PROGNOSTIC FACTORS IN UGANDIAN PATIENTS.

(E.) Primack, A.; Vogel, C. L.; Kyalwazi, S. K.; Ziegler, J. L.; Simon, R.; Anthony, P. P. (Uganda Cancer Inst., Kampala). *Cancer* 35(5):1357-1364, 1975.

A functional-anatomical staging system for hepatocellular carcinoma was studied for its prognostic significance. Historical, clinical, and laboratory aspects of the scheme were examined in 72 untreated patients with hepatocellular carcinoma. The median survival for the group was 1 month. The presence of a serum bilirubin concentration of greater than 2 mg/100 ml or weight loss greater than 25% of body weight were the poorest prognostic features. Other factors having prognostic significance were visible abdominal collateral circulation, ascites, tumor differentiation, and elevated serum levels of alkaline phosphatase, SGOT, α-fetoprotein, and proline hydroxylase. Analysis of prognostic factors suggested a modification and simplification of the staging classification devised at an International Symposium on Liver Cancer in Kampala; three prognostically different groups of Ugandan patients were defined. The authors suggest that the staging scheme presented serve as a frame of reference for comparison of prognostic features in different populations of patients with hepatocellular carcinoma.

4795 HISTOLOGICAL CHANGES IN LIVER BIOPSIES OBTAINED AT THE TIME OF INTESTINAL BYPASS PROCEDURES FOR MORBID OBESITY.

(E.) Krantz, B. E.; Schenken, J. R.; Swenson, S. A.; Vickstrom, D.; Pumphrey, H. (Univ. Nebraska Sch. Med., Omaha). *Nebr. Med. J.* 59(9):347-350, 1974.

Liver biopsies were performed in 46 patients undergoing jejunocolic bypass and on 107 patients undergoing jejunoileal bypass for morbid obesity (203-470 lb) or for complications of previous bypass procedures. Of 112 biopsies obtained at the time of primary bypass, 76% showed some degree of fatty change. Of 38 having a secondary bypass, 84% showed fatty liver. The majority of biopsies also had evidence of chronic portal or parenchymal inflammation, usually mild. Focal acute hepatitis, epithelioid granulomas and periportal fibrosis were evident in a few cases. In general, these changes were more commonly seen in patients following jejunocolic bypass. Histologic changes had usually progressed in 17 patients from whom liver biopsies had been obtained at the time of primary bypass and again during a second procedure 5 to 51 months later. It is concluded that liver biopsy should constitute an essential part of the prebypass evaluation of patients with morbid obesity.

4796 IMMUNOFLUORESCENT AUTOANTIBODY STUDIES IN THE DIAGNOSIS OF CHRONIC LIVER DISORDERS.

(E.) Doniach, D. (Middlesex Hosp. Med. Sch., London, England). *Rend. Gastroenterol.* 6(3):192-203, 1974.

Serum antibodies detected by immunofluorescence are reviewed in relation to differential diagnosis in chronic liver disease. The incidence of antinuclea antibodies (ANA) is highest in lupoid hepatitis, bu the ANA test is positive in 70-80% of patients with chronic active hepatitis (CAH) when Australia antigen-positive cases are excluded. The staining pattern is usually diffuse in CAH as opposed to speckled or nucleolar in primary biliary cirrhosis (PBC) and cryptogenic cirrhosis. Smooth muscle-related antibodies (SMA) are specific for CAH only if titer are greater than 80. Mitochondrial antibodies (AMA) are detected in 84-96% of patients with PBC; titers are high (200-6000) in about 1/2 the patient and moderate or low in the remaining. Liver/kidney microsomal antibodies (LKM) show a striking correlation with a form of CAH: the patients tend to be young and many progress to cirrhosis. Clinical and serological features are shown for six subgroups of CAH, the largest of which shows none of the serological markers. The other groups are Australia antigen-related (virus B), drug-induced, lupoid, PBC-related, and LKM-associated. Patients with lupoid hepatitis are mostly female and have SMA in addition to high titer ANA. The PBC-related cases are seen in much older women. Striking features of the LKM-associated cases are the lower frequency of ANA and SMA, the high proportion of males and the defined icteric onset. All forms of acute hepatitis are associated with a high incidence of SMA, which disappear on recovery; ANA, AMA, and LKM reactions are rare and/or transient. Australia antigen tests are usually negative in lupoid and PBC-related CAH. Post-operative jaundice associated with halothane anesthesia is associated with a 100-fold increase in LKM. It is concluded that the serum antibodies detected in liver diseases are probably not responsible for destruction of hepatocytes but can be considered markers of other underlying pathogenic processes. Their constant presence only in certain types of disease suggests that they are not an epiphenomenon.

4797 SUBSTRATE INCORPORATION INTO HEPATIC LIPIDS AND PROTEINS IN VITRO IN PATIENTS WITH PRE-β HYPERLIPOPROTEINEMIA. *(E.)* Stakeberg, H.; Schersten, T. (Sahlgrenska Hosp., Univ. Goteberg, Sweden). *Acta Med. Scand.* 197(3):217-223, 1975.

The role of the liver in pre-β-hyperlipoproteinemia was studied in 13 patients with types IIB and IV of the disease who presented for surgery with uncomplicated gallbaldder disease, (and in one, atherosclerotic abdominal aortic disease). Of these, five were fed a sucrose-enriched diet for 14 days prior to surgery. There were 40 controls, all presenting for surgery with uncomplicated gallbladder disease, and having no other known disorder. Of these, four were fed a sucrose-enriched diet for 14 days. No patients had known alcoholic problems or were on oral contraceptives. All fasted from 8 pm the day before until surgery at about 8 am. Liver biopsy was performed immediately and the liver slices prepared and incubated for determination of rates of glycerol and fructose incorporation into liver lipids and glycogen, determination of leucine incorporation into proteins, determinations of lipid phosphorus, glycogen, and protein, and determination of the rate at which labeled precursors were incorporated into triglycerides, phosphoglycerides, the fatty acid moeity of glycerides, and glycogen. Patients with the disease and on an ordinary diet had phosphoglyceride, glycogen, and protein concentrations similar to control values. The five fed sucrose showed a high triglyceride concentration (55 μM/g), low phosphoglyceride concentration (19.7 μM/g), high glycogen concentration (7.2 mg/100 mg) and normal protein concentration. Phosphoglyceride concentration in liver from patients with the disease on ordinary diet was the same as the control value. In diseased patients not given sucrose, glycerol was incorporated in triglyceride at a higher rate than that of controls. There was also a trend toward increased incorporation rate of this substrate into the fatty acid glyceride moiety. In the sucrose-fed diseased patients, glycerol was incorporated into triglyceride at the same rate as those on the ordinary diet (254 μM/g). However, incorporation of glycerol and fructose (51.0, 17.4, resp.) into hepatic phosphoglycerides were lower after sucrose feeding in diseased patients than those on ordinary diet. There was also a lower glycerol incorporation rate into glyceride fatty acid moieties in sucrose-fed patients (1.9 μM/g). Controls fed sucrose had a higher leucine incorporation rate into hepatic proteins than controls on ordinary diets. It is concluded that the vulnerability of hepatic phosphoglyceride and protein metabolism to sucrose is increased in patients with pre-β-hyperlipoproteinemia.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

4854 STUDIES ON PHOTOTHERAPY IN NEWBORN INFANTS. INFLUENCE ON PROTEIN BINDING OF BILIRUBIN AND SALICYLATE AND ON ACTIVITY OF ACETYLSALICYLIC ACID ESTERASE. *(E.)* Windorfer, Jr. A.; Faxelius, G.; Boreus, L. O. (Karolinska Hosp., Stockholm, Sweden). *Acta Paediatr. Scand.* 64(2):293-298, 1975.

Protein binding both of bilirubin and salicylate before and after phototherapy was studied in newborns with hyperbilirubinemia. The effect of light on acetylsalicylic acid esterase was also studied, and for comparison, parallel experiments were done on light-treated rabbits and on light-treated blood and plasma *in vitro*. Newborns (15) were subjected to phototherapy for 2-4 days for hyperbilirubinemia; five neonates from the same ward were used as control patients. Blood analyses were made before and after phototherapy. An increase was observed in hematocrit values and in the activity of the erythrocyte enzyme acetylsalicylic acid esterase. The elevation of the enzyme activity also could be produced in light-treated rabbits and *in vitro* after illumination of blood from adult volunteers. The binding of bilirubin to serum albumin and of salicylate to plasma proteins was not altered, nor were the concentrations of albumin or total proteins in plasma. The results indicate that light does not increase the unbound fraction of bilirubin in blood.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

4857 HALOTHANE-RELATED HEPATITIS. A CLINICAL STUDY OF TWENTY-SIX CASES. *(E.)* Moult, P. J. A.; Sherlock, S. (R. Free Hosp., London, England). *Q. J. Med.* 44(173):99-114, 1975.

The clinical details of halothane-induced hepatitis were reviewed in 26 cases. The mean body weight was 68.4 kg for the women and 74.4 kg for the men. No patients were considered where hepatitis might have been attributable to another anesthetic. None had either alcoholism or chronic liver disease. With the exception of four laparotomies and four craniotomies, the operations were relatively minor. All 26 patients became jaundiced within 12 days of halothane anesthesia. One patient gave a history of jaundice after an anesthetic 8 yr previously. Excepting two patients, all had 2, 3, or 4 exposures to halothane within a 3-month period. Eight patients had blood transfusions, seven of them within the previous month. Eight were given phenothiazine drugs and two coricosteriods postoperatively, and 16 were given antibiotics and two diphenylhydantoin preoperatively. Eight patients had delayed and unexplainable pyrexia as previously described in halothane-induced hepatitis. Treatment of fulminant hepatic failure was by dextrose infusion, oral neomycin, enemas, and vitamin K. All 11 patients who died were in fulminant hepatic failure. Two were treated by exchange transfusion. Jaundice in the 15 survivors lasted from 1-12 weeks. None developed any clinical or biochemical evidence of liver disease. The minimum thrombo-test in the fatal cases was 15% or less, while only three of the survivors had less than 15%. Mean body weight was 79.8 kg in fatal cases as opposed to 64.9 kg for survivors. All fatal cases became jaundiced within 7 days of the last anesthetic, while all who became jaundiced after this time survived. It is concluded that halothane-induced hepatitis should be regarded as a clinical entity, and prognosis is related to obesity and rapidity with which jaundice appears postoperatively.

4858 HEPATIC COMPLICATIONS OF ANTITUBERCULOUS THERAPY. *(E.)* Rossouw, J. E.; Saunders, S. J. (Groote Schuur Hosp., Capetown, South Africa). *Q. J. Med.* 44(173):1-16, 1975.

The frequency of hepatic reactions to drug treatments for pulmonary tuberculosis and patterns for each drug (sensitization time, associated hypersensitivity, biochemical findings and prognosis) were investigated. Records of 7492 patients admitted to two hospitals for pulmonary tuberculosis between 1960 and 1973 were included in the study. Drug hepatitis was diagnosed if the patient became clinically jaundiced or had at least two abnormal liver function tests. Patients with abnormal baseline liver function tests, or who had a history of alcoholism, recent blood transfusion, liver disease, contact with infectious hepatitis or exposure to other drugs were excluded. The reaction was assigned to a particular drug: if the patient was on the drug for at least 3 weeks preceeding the reaction; if after withdrawal, rechallenge reproduced the reaction; if after withdrawal, rechallenge with other drugs did not reproduce the reaction; or after withdrawal of the suspected drug but with continuation of other drugs, the reaction settled. Of the 7492 cases, there were 24 cases of hepatitis (0.32%); 14 cases from another hospital were added. Para-aminosalicyclic acid was implicated in 16 cases, while in 12 cases it was either this agent or isonicotinic hydrazide. The latter alone was responsible for three cases, ethionamide for one, and multiple drugs for three. The three isonicotinic hydrazide patients were over 50 yr of age, as compared to five in this age bracket in the remaining 35 cases. The time between the starting of the drug and the first symptom was under 90 days in all cases. Most (89%) of the patients had premonitory symptoms preceeding the jaundice, including rash (23 patients), pyrexia, and gastrointestinal disturbances. Clinical jaundice developed in all but five. Skin lesions were found in 80%. Pyrexia was common in the para-aminosalicyclic acid (69%) and para-aminosalicyclic acid plus isonicotinic hydrazide (85%) groups, and lymphadenopathy was found in 46% of both. Hepatomegaly was almost universal. No patients with para-aminosalicyclic acid hepatitis died, while there was a 25-33% mortality in the other groups. It is suggested that such patients be kept under close surveillance and drug therapy stopped as soon as warning symptoms appear.

4859 THE COMPETING RISKS OF TUBERCULOSIS AND HEPATITIS FOR ADULT TUBERCULIN REACTORS. *(E.)* Comstock, G. W.; Edwards, P. Q. (Sch. Hyg. Public Health, Johns Hopkins Univ., Baltimore, Md.). *Am. Rev. Respir. Dis.* 111(5):573-577, 1975.

The competing risks of tuberculosis and isoniazid-associated hepatitis were estimated according to the best evidence now available. Tuberculosis risks were derived from two sets of data on adult reactors to 5 TU of purified protein derivative: average annual tuberculosis case rates during a 20-yr period among reactors in Muscogee County, Georgia, and Russell County, Alabama; and average annual case rates during a 10-yr period among reactors given placebo in mental hospitals in Georgia, Massachusetts, and Wisconsin. Hepatitis risks were derived from U.S. Public Health Service information on persons over 20 yr who had taken isoniazid for up to 1 yr. Lifetime tuberculosis risks/1000 reactors and the number of tuberculosis cases preventable by isoniazid prophylaxis are shown according to race, sex, and age (25-65 yr). Estimated hepatitis rates/1000 persons are given for specified ages, as are the expected number of cases among 1000 reactors completing 1 yr of isoniazid treatment. The ratio of tuberculosis cases preventable by treatment to hepatitis cases occurring during treatment is specified according to race, sex, and age. The probability of developing hepatitis during 1 yr of treatment with isoniazid ranges from 2.4/1000 adults younger than 35 yr to 19.2/1000 at 55-64 yr. It is concluded that the upper age limit for isoniazid prophylaxis should be set at 45 yr for reactors without additional risk factors. With additional risk factors, such as recent conversion or household exposure, abnormal chest roentgenogram, diabetes, or long-term corticosteroid therapy, it is probably wise to give preventive treatment to all but the very old.

4860 DIAGNOSIS OF ACUTE SYPHILITIC HEPATITIS. *(Rus.)* Zeldin, V. E.; Storozhakova, I. A.; Vishneevtskii, A. M.; Kelner, R. I. (Cent. Res. Inst. Dermatol. Syphilol., Moscow, USSR). *Klin. Med. (Mosk.)* 52(11):133-135, 1974.

A case is reported of acute syphilitic hepatitis in a 43-yr-old man hospitalized with complaints of anemia, loss of appetite, nausea, jaundice, itching and subfebrile fever. No pathology of the urinary system was observed. The liver was enlarged 4 cm beyond the costal arch. Blood values upon admission were Hgb 13 g%; erythrocytes 4,100,000 mm^3; color index 0.92; leukocytes 8,000; ESR 22 mm/hr. Urine values were: nitrogen 22 mg%; bilirubin 4.72 mg%; cholesterol 252 mg%; SGOT 48 U; SGPT 50 U; whole protein 8.17 g%; albumin 39.6%; globulin α_1 = 9.4%; α_2 = 13.6%; β = 15.3%; γ 22.1%. The albumin-globulin coefficient was 0.66. The case was diagnosed as chronic hepatitis and prednisolone treatment (15 mg/day) was prescribed with glucose, cocarboxylase and vitamins. On the 16th day of hospitalization moist papules were observed in the anal region. Wassermann reaction was ++++ (titre 1:320). Kahn's and Sachs-Witebsky tests were strongly positive. Roseola elements were observed on the body skin; papule-like formations, on the palms and feet. The diagnosis was recurrent secondary syphilis and acute syphilitic epithelial hepatitis. Treatment by penicillin (14,000,000 U) was prescribed.

The blood and urine values returned to normal 1 month after the treatment began. Wassermann and precipitation tests continued to be strongly positive. The patient was discharged in a satisfactory condition. It is indicated that clinically and morphologically, acute syphilitic hepatitis has much in common with viral hepatitis except for certain specific features: 1) jaundice is accompanied by eruptions on the skin and mucous membranes; 2) the process in the liver is quickly reversed as a result of antisyphilitic treatment; and 3) a sharp drop in the albumin content and an increase in the globulin content is observed.

4861 HEPATITIS DUE TO AFLATOXICOSIS: AN OUTBREAK IN WESTERN INDIA. *(E.)* Krishnamachari, K. A. V. R.; Nagarajan, V.; Bhat, R. V.; Tilak, T. B. G. (Indian Counc. Med. Res., Hyderabad). *Lancet* 1(7915):1061-1063, 1975.

An epidemic of hepatitis in parts of western India was reported; the syndrome was characterized by icterus, rapid onset of signs of portal hypertension, ascites, and a high mortality rate. The disease affected man and dogs and was associated with the consumption of maize heavily contaminated with *Aspergillus flavus*; 106 of 397 patients died. In five maize samples obtained from affected households, the aflatoxin levels ranged between 6.25 and 15.6 ppm; thus, the patients would have ingested 2-6 mg aflatoxin/day for several weeks. Detectable levels of aflatoxin B_1 were found in 2 of 7 serum samples. A specimen of liver obtained at necropsy showed bile duct proliferation and giant cells. The observations indicate that staple foodgrains can become sufficiently infected to result in disease, and that there is a need for divising means of averting such contamination.

4862 CHOLESTATIC HEPATITIS AFTER ADMINISTRATION OF FURAN DERIVATIVES. *(E.)* Engel, J. J.; Vogt, T. R.; Wilson, D. E. (Abraham Lincoln Sch. Med., Univ. Ill., Chicago). *Arch. Intern. Med.* 135 (5):733-735, 1975.

A case was reported of a patient who developed jaundice following nitrofurantoin therapy and subsequently developed a second episode of liver injury following intravaginal administration of a mixture of nifuroxine and furazolidone. Liver function tests following nitrofurantoin therapy for a urinary tract infection (300 mg/day, 7 days) showed liver enzyme values of: SGOT, 121 U; SGPT, 256 U; alkaline phosphatase, 350 IU. The patient was treated for vaginal trichomoniasis 1 week later and received two vaginal suppositories, each containing furazolidone (5 mg) and nifuroxime (7.5 mg); liver enzyme values that day were SGOT, 49 U; SGPT, 96 U; and alkaline phosphatase, 169 IU. The enzyme levels 4 days later rose to: SGOT, 256 U; SGPT, 325 U; and alkaline phosphatase, 760 IU. Fractionation of the alkaline phosphatase showed that it was of liver origin. After discontinuing the suppository therapy, the liver enzymes slowly returned to normal. The data suggest cross-sensitivity between the two furan derivatives and that such cross-sensitivity of chemically related compounds be considered even when they are administered by different routes.

4863 THREE CASES OF SEVERE ACUTE HEPATIC FAILURE OCCURRED AFTER REPEATED HALOTHANE ANESTHESIA. *(E.)* Kosaka, Y.; Matsuda, Y.; Tagawa, S.; Terada, M.; Akeda, S.; Nakagiri, S.; Tameda, Y.; Tsujita, E.; Kondo, I.; Shiomi, Y.; Kawarada, R.; Okuda, Y. Acute Viral Hepatitis

4870 THERAPEUTIC EFFECT OF GLUCOCORTICOIDS ON THE COURSE OF VIRAL HEPATITIS IN CHILDREN WITH REGARD TO THE PRESENCE OF AUSTRALIA ANTIGEN. *(Pol.)* Kossakowski, R.; Sokolewicz, E.; Szelag, O. (Acad. Med., Bialystok, Poland). *Pediatr. Pol.* 48 (10):1197-1202, 1973.

Fifteen children (aged 3 months to 12 years) with viral hepatitis and serum Australia antigen (AuAg) and 15 children of the same age with viral hepatitis but without AuAg were treated with 1 mg/kg/day prednisone for 3-6 weeks. AuAg-positive children had a longer history of the disease and were ill longer (up to 147 days) before therapy than AuAg-negative children (maximum duration 71 days). However, the thymol turbidity test, SGPT and SGOT activity, and hepatomegaly were less pronounced in AuAg-positive than in AuAg-negative children. After prednisone therapy the Au Ag-negative children showed rapid clinical and biochemical improvement, while AuAg-positive children showed only transient improvement; 2 weeks after discontinuation of the therapy the serum transaminase activities and hepatomegaly recurred.

4871 CELL-MEDIATED IMMUNITY IN ACUTE AND CHRONIC HEPATITIS. *(E.)* Wands, J. R.; Perrotto, J. L.; Alpert, E.; Isselbacher, K. J. (Harvard Med. Sch., Boston, Mass.). *J. Clin. Invest.* 55(5):921-929, 1975.

Peripheral lymphocytes from 22 patients (18 men and 4 women, aged 18-65 yr) with acute hepatitis, chronic active hepatitis, or chronic persistent hepatitis and from nine controls were tested for *in vitro* cytotoxicity and blast transformation. Of the 22 patients, 17 were positive and five were negative for hepatitis-B surface antigen (HB$_s$Ag). Cytotoxicity was measured by ^{51}Cr release into the medium from labeled Chang cells after 6-hr incubation with peripheral lymphocytes at a lymphocyte target cell ratio of 200:1. Concomitant 72-hr incubation studies were performed to assess thymus cell-dependent (T) lymphocytic function as measured by concanavalin A (Con A)-stimulated incorporation of tritiated thymidine (blast transformation) and by cytotoxicity. Lymphocytes from patients with acute hepatitis were significantly cytotoxic to Chang cells compared with control lymphocytes (12.71% *versus* 2.71%). Lymphocytes from patients with acute and chronic hepatitis were less cytotoxic when incubated with autologous and homologous HB$_s$Ag-positive serum; and lymphocytes from patients with HB$_s$Ag-positive and negative acute, chronic active hepatitis, or chronic persistent hepatitis were as cytotoxic as normal controls when stimulated with Con A. Lymphocytes from chronic active hepatitis patients on prednisone therapy (30 or 50 mg/day for 2.5 months) showed marked depression of cytotoxicity when stimulated with Con A. These studies show that patients with acute hepatitis have circulating T lymphocytes that are capable of causing destruction of Chang liver cells; that patients with acute and chronic hepatitis have a serum factor(s) that inhibits spontaneous and induced lymphocyte cytotoxicity and blast transformation; and that prednisone treatment appatently inhibits lymphocyte toxicity in patients with chronic active hepatitis.

4872 PROPHYLAXIS OF POSTTRANSFUSION HEPATITIS: BIOCHEMICAL TESTS FOR RESEARCH IN BLOOD DONORS. *(Fr.)* Plomteux, G. (Lab., Med. Chem., Liege, Belgium). *Ann. Gastroenterol. Hepatol. (Paris)* 10(5):401-411, 1974.

Patients with acute viral hepatitis (110) were checked weekly until 34 parameters relating to hepatic function indicated normalization of hypertransaminasemia. The frequency of perturbation of the parameter and degree of global sensitivity of the test in the population studied were calculated for each parameter. It was found that the highest frequencies of perturbations were for SGPT (100.00%), SGOT (98.21%), and ornithine carbamoyltransferase (OCT), (85.71%). The coefficients of sensitivity for the tests for the three substances were, resp., 118.43, 79.29, and 50.24. In 2 yr, 5,397 U of blood were transfused and assayed for degree of perturbation in the concentration of SGPT, SGOT, and OCT. One or more of the enzymes occurred in abnormal concentrations in 6.32% of the donors, but only 2.68% showed perturbation of the concentrations of all three enzymes and in the relative order determined in the tests on hepatitis patients. The latter units of blood were classified as biochemically suspect if the value of the SGPT was at least 100 mIU. A number of patients who had received both normal and suspect blood were followed up. A statistically significant difference was found in the subsequent evolution of plasma concentrations of the three enzymes in the recipients of normal *versus* suspect blood. In 2 examples of the development of recipients of suspect blood, the plasma concentrations of the three enzymes increased tremendously by the fourth or fifth week after transfusion, and then gradually returned to normal.

4873 HOST COMPONENTS IN HEPATITIS B ANTIGEN. *(E.)* Burrell, C. R. (Edinburgh Univ. Med. Sch., Scotland). *J. Gen. Virol.* 27(2):117-126, 1975.

Radioimmunoassays were performed to determine if 20-25 nm hepatitis antigen (HB Ag) particles are intrinsically composed of normal serum components, modified by hepatitis B virus infection in the host to express a unique virus-specific antigenic character, or whether these particles represent primarily virus-code material, associated in some preparations with contaminating serum components. Purified ^{125}I-labeled 20-25 nm HB Ag particles gave low affinity immunoprecipitation reactions with antisera to several normal serum components; the reactions were immunologically distinct from the reaction due to the classical HB Ag surface determinant. These additional antigenic determinants were acid-stable and tightly bound to the particles; they could not be released by treatment with Tween 80 or ether, but were removed by protease digestion with preservation of particle integrity. It was not possible to distinguish whether they were due to the presence of trace amounts of partly denatured serum components, or to a weak cross-reaction with antigens present in normal serum. Some cross-reaction with antigens in normal serum, in particular involving the superficial carbohydrate moieties of HB Ag, would not be surprising in sensitive assays. No evidence was found for native antigenic material, present in normal serum or normal liver cells, being integral to the structure of these particles.

4874 SERUM IMMUNOGLOBULIN M (IgM) VALUES IN VIRAL HEPATITIS PATIENTS.

(E.) Ene, M.; Roman, D.; Luca, V.; Duda, R. (Iasi Inst. Med. Pharm., Rumania). *Rev. Med. Chir. Soc. Med. Nat. Iasi* 78(3): 659-662, 1974.

Serum immunoglobulin M (IgM) levels were measured by radial immunodiffusion in 80 patients with jaundice, of whom 68 had viral hepatitis and 12 (controls) had other hepatobiliary diseases. In 12 viral hepatitis patients with Australia antigen (HB$_s$Ag) and eight without HB$_s$Ag but with a long period of incubation (more than 60 days), the mean serum IgM value was 197 mg/100 ml or close to the control value of 144 mg/100 ml. These 20 patients were assumed to have virus B hepatitis. The remaining 48 viral hepatitis patients without HB$_s$Ag had a significantly higher IgM level of 273 mg/100 ml. This group was considered to have virus A hepatitis. The results suggest that determination of serum IgM within the first 10 days of jaundice would permit differentiation of the two forms of viral hepatitis according to immunologic criteria.

4875 PROGNOSTIC SIGNIFICANCE OF SUBACUTE HEPATIC NECROSIS IN ACUTE HEPATITIS.

(E.) Ware, A. J.; Eigenbrodt, E. H.; Combes, B. (Univ. Texas Southwest. Med. Sch., Dallas). *Gastroenterology* 68 (3):519-524, 1975.

A retrospective analysis was made of 57 patients treated during the period 1967-1973 with the lesion of subacute hepatic necrosis in the setting of acute hepatitis. Of the 57 patients, 40% were male and 60% female, with 63% under 30 yr of age, and 21% over 40 (age range of 14-88 yr). Epidemiology included contact with hepatitis (25%), blood transfusion (4%), i. v. drug use (26%), and hepatotoxic drugs (12%). Of the 49 patients so tested, 67% carried Australia antigen (HB$_s$Ag) in their sera. Excluding the seven patients considered to have a drug-related liver injury, the incidence of HB$_s$Ag positivity rises to almost 80%. The drugs implicated as the probable etiologic agent in these seven were halothane (three), aldomet (two), isoniazid, and propylthiouracil. Of the 57 patients, 14 were lost to follow-up but were doing very well when last seen. One paitent died with massive hepatic necrosis 6 weeks after her biopsy had shown the lesion of subacute hepatic necrosis. The remaining 42 were observed from 2-73 months (average 19 months). Eight patients progressed to chronic active liver disease, one of whom died in hepatic failure after 14 months of continuous disease. In the other 34 patients, liver function tests returned to normal and remained so without therapy. In managing patients with subacute hepatic necrosis, high dose steroid therapy was instituted on making the diagnosis unless clinical and biochemical improvement was already underway. Thus, steroids were more likely given to the most seriously ill patients. The patient who progressed to massive necrosis did so despite high dose prednisolone therapy. Not one of the eight patients who developed chronic active liver disease, however, received steroid therapy during their acute illness, although a number of them have since been so treated. Thus the results of this study do not support the view that steroid therapy in acute hepatitis may actually encourage the development of chronic disease. Repeat biopsies from 10 months to 6 yr after the initial biopsy in nine of the 34 patients who underwent biochemical resolution showed two of them with inactive postnecrotic cirrhosis. The incidence of these complications developing in patients with subacute hepatic necrosis was about 30% in this study. These findings add qualititive support to the position that liver biopsy findings bear important prognostic value in patients with acute hepatitis.

4876 AUSTRALIA-ANTIGEN (HB$_s$Ag) AND HEPATITIS IN CHILDHOOD.

(Ger.) Hellwege, H. H. (Univ. Clin. Pediatr., Hamburg-Eppendorf, Germany). *Monatsschr. Kinderheilkd.* 122(12):893-899, 1974.

Transient Australia antigen (HB$_s$Ag) was detected in sera from two children of 12 with acute sporadic hepatitis who had not been exposed to potential parenteral infective agents. One of these had a long lasting close contact with a chronic HB$_s$Ag carrier. Five of seven children with acute hepatitis following blood transfusions were HB$_s$Ag-positive. In all cases of acute hepatitis, whether HB$_s$Ag positive or negative, the illness was transient, and persistence of HB$_s$Ag never occurred. Five of eight children with chronic active hepatitis were HB$_s$Ag carriers. Parenteral exposure to potentially virus B-containing infective agents could be excluded in every case. Antinuclear antibodies were detected in the sera of two HB$_s$Ag-negative patients. During 15 months sera of 71 polytransfused children with hemophilia were tested serially. In this period five children developed acute hepatitis: two of them were chronic HB$_s$Ag carriers; and in one boy HB$_s$Ag could be detected only for a short time. When serum bilirubin and transiminase levels normalized, one chronic HB$_s$Ag carrier became negative. Two patients with hepatitis were known as chronic HB antibody (HB$_s$Ab) carriers. Antibodies against HB$_s$Ag were detected in sera of 26 patients with hemophilia without liver disease. More boys than girls suffering from acute and chronic hepatitis could be observed. The boys were predominating in both HB$_s$Ag-positive and negative groups. The incidence of HB$_s$Ag detection in these children suggests that Virus B-infection may play an important role in the pathogenesis of chronic active hepatitis in childhood.

LIVER AND BILIARY TRACT

Chronic Hepatitis

4899 CLOTTING AND FIBRINOLYTIC ACTIVITY OF BLOOD IN CHRONIC LIVER DISEASE. *(Pol.)* Kaniak, J.; Kotschy, M.; Kowal-Gierczak, B.; Plamieniak, L. (Acad. Med., Wroclaw, Poland). *Pol. Tyg. Lek.* 29(38): 1621-1624, 1974.

The blood clotting system and fibrinolysis were investigated in 60 patients with chronic liver disease. These patients consisted of 30 with liver necrosis, 15 with chronic hepatitis, and 15 with liver metastases of malignant neoplasms. Patients with cirrhosis showed reduced blood clotting and increased fibrinolytic activity (decrease in fibrinogen, prothrombin, factors VII and IX, a prolonged Stypven-cephalin time, low plasminogen values, shortened fibrinolysis time, and reduced values for antiplasmin and antithrombin). Patients with liver metastases showed increased blood clotting and decreased fibrinolytic activity, as indicated by increased serum thromboplastic activity in the Biggs-Douglas test: increased values of prothrombin and fibrinogen; somewhat low values for plasminogen; and a prolonged fibrinolysis time. Results in patients with chronic hepatitis were not specific and were in the lower normal range. Low values for prothrombin, factors VII and IX, and fibrinogen could be a manifestation of decreased synthesis by injured liver cells. Low values of fibrinogen, plasminogen, antiplasmin, and antithrombin could also result from intensified activation of fibrinolysis often observed in chronic liver disease.

4900 SYSTEMIC MANIFESTATIONS ASSOCIATED WITH CHRONIC AGGRESSIVE HEPATITIS. *(Fr.)* Geubal, A. (Saint-Pierre Univ. Clin. Louvain, Belgium). *Acta Gastroentero. Belg.* 37(4-5):192-206, 1974.

A retrospective study was made of 53 patients with histologically confirmed chronic aggressive hepatitis from clinical, serological, and pathological information available when the hepatitis was diagnosed or later. Systemic manifestations occurred more than twice as often in women (21 of 28) as in men (9 of 25). The most common systemic manifestations involved the skin (19 cases) and joints (15), but they were also found in the endocrine system (9 cases), kidneys (4), blood (3), gastrointestinal tract (2), lymphatic system (2), muscles (1), heart (1), and pleura and pericardium (1); 3 patients had paraproteinemia. Associated disorders consisted of clinical or preclinical diabetes (18 cases), neuropsychiatric disorders (8), peptic ulcer (5), and allergies (8). The severity of systemic manifestations was not related to the extent of liver malfunction nor to immunoglobulin levels. Antithyroid antibodies were detected in 62% of the patients, antigastric antibodies in 28%, and Australia antigen in 9 of the 30 studied. The severity of systemic manifestations was greatest in patients who were negative for Australia antigen on serum immunoelectro-osmophoresis. It was confirmed that anti-smooth muscle antibodies and Australia antigen are not found in the same patient, and antinuclear factor was associated with Australia antigen in only 1 case. Total hemolytic complement and B_1A globulin levels were significantly decreased in patients with systemic manifestations. No correlation was found between B_1A globulin concentrations and the Australia antigen titer. Complement titers were affected both by the extent of liver malfunction and by the existence of systemic lesions, particularly renal ones. In most patients, complement titers decreased during exacerbations of chronic aggressive hepatitis. The extrahepatic lesions found in these patients and the associated serological anomalies suggest that chronic aggressive hepatitis is an autoimmune disease.

4901 CELLULAR AND HUMORAL IMMUNITY TO HEPATITIS-B SURFACE ANTIGEN IN ACTIVE CHRONIC HEPATITIS. *(E.)* Lee, W. M.; Reed, W. D.; Mitchell, C. G.; Galbraith, R. M.; Eddleston, A. L. W. F.; Zuckerman, A. J.; Williams, R. (King's Coll. Hosp. Med. Sch., London, England). *Br. Med. J.* 1(5960):705-708, 1975.

Although hepatitis-B surface antigen (HB_sAg) may be persistently present in the serum in a few cases of active chronic hepatitis, the cause of the disease in most patients in unknown. Studies carried out on 39 HB_sAg-negative patients with active chronic hepatitis revealed the presence of cell-mediated immunity to HB_sAg in 24 (62%), suggesting a high frequency of previous infection with hepatitis-B virus. Hepatitis-B surface antibody was detectable by ra-

ioimmunoassay in six patients, in all of whom HB$_s$Ag
omplexes were present in the serum on electron mi-
roscopy. Patients with HB$_s$Ag-positive active chron-
c hepatitis (12) were also studied and eight, in-
luding all those untreated at the time, showed a
ellular response to the antigen. Evidence of sen-
itization to a liver-specific cell surface lipopro-
ein was found with similar frequency in both groups.
hese results are consistent with the hypothesis that
epatitis-B virus is important in initiating the
isease in many cases of active chronic hepatitis
nd that sensitization to the liver cell membrane
ntigen is the autoimmune process responsible for
erpetuation of the liver injury.

902 HAEMOLYTIC COMPLEMENT, ANTICOMPLEMENTARY ACTIVITY AND HEPATITIS B ANTIGEN IN SERA
F PATIENTS WITH CIRRHOSIS OF THE LIVER. *(E.)* Kel-
ar, S. S.; Karhade, N. V.; Kotwal, S. E. (Med. Coll.,
urangabad, India). *Indian J. Med. Res.* 63(1):41-44,
975.

era from 50 patients with liver cirrhosis (34 men
nd 16 women, mean age 34.5 yr) were studied for the
resence of hepatitis B antigen (HB Ag), anticomple-
entary activity, and level of hemolytic complement.
he latter two tests were done within 2 hr of sample
ollection to reduce artifacts. Of the 50 sera, 15
amples (30%) showed HB Ag by the immunoelectroosmo-
horetic technique but none contained hepatitis B
ntibody (HB Ab). Only two patients showed anticom-
lementary activity; both were negative for HB Ag
nd HB Ab. In the remaining 48 cases, hemolytic com-
lement levels (mean 3.6 U) were significantly lower
han levels (mean 7.2 U) in sera from 25 healthy con-
rols. Further analysis showed that the hemolytic
omplement levels were significantly reduced in both
B Ag-positive and negative cases compared with nor-
al controls. Differences in complement levels be-
ween the HB Ag-positive and negative groups were not
ignificant. Reduction of hemolytic complement may
e due to reduced synthesis by the damaged liver or
o its utilization in possibly pathogenic mechanisms.
t is postulated that the first view is correct and
hat a cell-mediated response is involved in hepatic
amage in HB Ag-associated cirrhosis.

903 SERUM IMMUNOGLOBULINS AND ANTIBODIES IN RELATIVES OF PATIENTS WITH CHRONIC ACTIVE
EPATITIS (CAH). *(E.)* Chiaramonte, M.; Borrelli,
.; Sturniolo, G. C.; Fagiolo, U.; Naccarato, R. (Inst.
ed. Pathol., Univ. Padua, Italy). *Rend. Gastroen-
erol.* 6(3):205-206, 1974.

n an attempt to determine if a familiar abnormality
f the immune response is involved in the develop-
ent of chronic active hepatitis from acute hepa-
itis, 78 close relatives of nine patients with chron-
c hepatitis (five HB Ag-positive and four HB Ag neg-
ative) were investigated for HB Ag (counterelectro-
horesis), serum immunoglobulins (radial immunodif-
fusion), antinuclear and anticytoplasma antibodies
RA-latex test), OCT, serum albumin and γ-globulin.
ll relatives were HB-negative. Serum antibodies
ere not significantly increased compared with con-
rols. Immunological changes were found only in families of two HB Ag-positive and two HB Ag-negative patients. Mild biochemical changes were also evident in some subjects.

4904 ASYMPTOMATIC AUTOIMMUNE LIVER DISEASE IN SCLERODERMA. *(E.)* Gupta, M. M.; Warnes, T. W.; Watson, L. (Univ. Coll. Hosp., London, England). *Postgrad. Med. J.* 51(593):185-189, 1975.

A case of scleroderma with asymptomatic autoimmune liver disease is reported. The 54-yr-old female patient presented with features of CRST syndrome (calcinosis, Raynaud's phenomenon, sclerodactyly, and telangiectasia). Routine investigation revealed elevated plasma alkaline phosphatase (63 King-Armstrong U/100 ml). Separation of the isoenzymes of alkaline phosphatase by electrophoresis on polyacrylamide gels showed that the elevated enzyme was of hepatic origin; the presence of antimitochondrial, antinuclear, and smooth muscle antibodies in the serum suggested an associated autoimmune liver disease, which was confirmed by liver biopsy. Biopsy showed slight cholestasis and inflammatory cell infiltration around the portal system with bile ductule proliferation and reticulin increase extending into lobules. The histologic appearance was compatible with active chronic hepatitis progressing to cirrhosis. Routine measurement of serum alkaline phosphatase in all patients with scleroderma is indicated as a simple screening procedure for autoimmune liver disease.

4905 IMMUNOSUPPRESSIVE THERAPY IN CHRONIC HEPATITIS IN CHILDREN. *(E.)* Rabenda, C.; Rudkowski, Z. (Med. Acad., Wroclaw, Poland). *Mater. Med. Pol.* 6(3):202-206, 1974.

After failure of corticotherapy, six children (aged 2-9 yr) with chronic hepatitis were treated with immunosuppressive drugs (6-mercaptopurine, cyclophosphamide, and azathioprine). Permanent remissions lasting from 2 months to 4 yr were obtained in five cases. No side effects of the drugs were observed apart from moderate leukopenia and thrombocytopenia. Infections were not more frequent or more severe in the treated children. Varicella in one child ran a mild course. Case reports are presented for three children treated with 6-mercaptopurine followed by cyclophosphamide (0.5-1.0 mg/kg/day) or cyclophosphamide plus aziothioprine (0.8 mg/kg/day). 6-Mercaptopurine was without effect in one child who subsequently responded to cyclophosphamide therapy. Liver and spleen decreased in size as early as 2 weeks after immunosuppressive therapy, followed by disappearance of antinuclear antibodies from the serum and reversion of biochemical indexes to normal. Further trials of immunosuppressive therapy in children with chronic hepatitis appear warrented.

4906 IMMUNOSUPPRESSIVE TREATMENT OF CHRONIC HEPATITIS. *(Pol.)* Stempien, R.; Bergiel, A.; Fabianowski, J. (Acad. Med., Lodz, Poland). *Pol. Tyg. Lek.* 29(37):1583-1586, 1974.

A total of 29 patients (12 women and 17 men, aged 30-50 yr; av. 43.6 yr) with confirmed chronic hepatitis were treated with azathioprine (100-150 mg/day for 2-4 weeks followed by a maintenance dose of 50 mg/day) and prednisolone (15-20 mg/day). The duration of therapy ranged from 6-14 months; most patients are still being treated. The progress of disease was arrested in 23 of the 29 patients, and in some cases a complete remission was obtained. Marked clinical and biochemical improvement occurred in 6, some improvement in 17, no change in 5, and deterioration in 1. A decrease in hepatomegaly was observed in 20 of 29; of splenomegaly in 12 of 14; of ascites in 4 of 4; disappearance of telangiectasia in 5 of 10; and of palmar erythema in 5 of 13. Bilirubin levels returned to normal in 11 of 16 and improved in 2; albumin levels in 6 of 14 and 2 of 14, resp.; protein levels in 4 of 7 and 1 of 7, resp.; gamma globulin in 6 of 29 and 10 of 19, resp.; the thymol turbidity test in 7 of 29 and 13 of 29, resp.; and SGPT in 18 of 25 and 4 of 25, resp. Viral hepatitis preceded the disease in 24 cases; in 19 cases it occurred 4-18 months before immunosuppressive therapy was instituted. There were no serious side effects of treatment: 6 patients had brief episodes of upper respiratory infection and 10 showed transient decreases in the WBC or platelet count.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

4912 HOST FACTORS CAUSING INCREASED SUSCEPTIBILITY TO INFECTION IN PATIENTS WITH LAENNEC'S CIRRHOSIS. *(E.)* Andersen, B. R. (Abraham Lincoln Sch. Med., Univ. Illinois, Chicago). *Ann. NY Acad. Sci.* 252:348-352, 1975.

Infection is one of the common precipitating factors of hepatic coma in patients with cirrhosis and is the immediate cause of death of about 1/2 of patients with Laennec's cirrhosis. Facets of the host-defense mechanisms that appear to be most important in preventing the pyogenic infections that predominate in cirrhotics are the reticuloendothelial system, antibodies, complement, and neutrophilic granulocytes. Current knowledge about the functional capacity of these systems in cirrhotics is reviewed with emphasis on the complement system. Granulocytes of cirrhotic patients apparently have no significant functional defect and there is clearly no deficiency in antibodies function. Studies of reticuloendothelial function in cirrhotic rats demonstrated that i.v. injected bacteria were normally cleared from blood, although there was a delay in bacterial killing in the animals. A study of 12 cirrhotic patients at a VA hospital showed a decrease in complement components, especially C3 (7/12), C4 (1/2), and C3 proactivator (4/12). Of 11 patients tested for total hemolytic complement, eight had below-normal levels. These complement deficiencies may provide a less than optimal chemotactic and phagocytic stimulus for the granulocytes of the cirrhotic patient. The poor chemotactic response of the patients to their own serum was initially attributed to the depression of complement components. However, normal serum added to patient serum did not correct the problem. A serum inhibitor of chemotaxis was demonstrated in most patients with advanced Laennec's cirrhosis; the inhibitor was quite labile and quickly lost at room temperature.

4913 FOLATE DEFICIENCY IN THE ALCOHOLIC - ITS RELATIONSHIP TO CLINICAL AND HAEMATOLOGICAL ABNORMALITIES, LIVER DISEASE AND FOLATE STORES. *(E.)* Wu, A.; Chanarin, I.; Slavin, G.; Levi, A. J. (Northwick Park Hosp., Harrow, England). *Br. J. Haematol.* 29(3):469-478, 1975.

Clinical and laboratory observations were made on 84 patients (56 men and 28 women, aged 27-78 yr) regularly taking more than 80 g of alcohol/day. Macrocytosis was present in 84.5%, but only 13% were anemic. Of 57 bone marrow samples, 27 were abnormal, and 20 showed megaloblastic changes, most-

mild in degree. Serum, RBC, and liver folate
vels were reduced in 28%, 35%, and 31% of the pa-
ents, resp. Liver folate deficiency was more
vere in those patients, more often female, who
l inadequate diets or drank wine and spirits
ther than beer. The amount of alcohol consumption
l extent of liver damage did not affect folate
atus. These findings suggest that folate defi-
ency is common among alcoholics in England. How-
er, this study emphasizes that alcohol can cause
crocytic and megaloblastic changes by two separate
chanisms, one secondary to folate deficiency,
other by a direct toxic effect. The direct toxic
fect plays a more significant role in alcoholics
o take an adequate diet, as did most of the pa-
ents in this study. Many of the patients had
crocytosis, sometimes with megaloblastosis, in
e absence of folate deficiency, emphasizing the
rect toxic effect of alcohol on the developing
ythroblast. The findings of this study are not
mpatible with the suggestion that negative folate
lance always precedes megaloblastic conversion.

Cirrhosis

18 INTRAVENOUS VASOPRESSIN IN PATIENTS WITH PORTAL HYPERTENSION: ADVANTAGES OF CON-
NOUS INFUSION. *(E.)* Thomford. N. R.; Sirinek, K.
(Ohio State Univ. Coll. Med., Columbus). *J. Surg.*
s. 18(2):113-117, 1975.

ntinuous infusion and bolus injection of vasopres-
n were compared in reduction of portal vein pres-
re and adverse hemodynamic side effects. The stu-
included seven patients with Laennec's cirrhosis
o had hemorrhages from esophageal varices. Poly-
hylene catheters were inserted into the portal
in, superior vena cava, and one radial artery to
nitor pressures and determine cardiac output. Af-
r 72 hr each patient was daily stabilized for 30-
min and tested for 60 min for the hemodynamic ef-
cts of the vasopressin. Recordings were made at
5, 15, 30, 45, and 60 min. Bolus administration
nsisted of 15 U lysine-vasopressin in 100 ml 5%
xtrose given in 5 min. Infusion consisted of 0.4
lysine-vasopressin/ml 5% dextrose at 100 ml/hr.
e two types of administration were alternated dai-
. The bolus injections caused severe cramping and
dominal pain within 60 sec, and prompted defeca-
on and urination within 5 min, as well as causing
usea in all patients. Premature arterial contrac-
ons occurred in seven patients and persisted as
ng as 30 min. During the injection, systolic pres-
re increased briefly from 117 to 138 mm Hg. A
gnificant brachycardia occurred and persisted for
min. Average portal pressure decreased from 366
saline to 294 mm saline after 5 min and gradually
increased to 315, 329, and 341 mm after 15, 30 and 60 min, resp. Average cardiac output decreased from 6.7 to 5.6 liters/min at 30 min and was still significantly decreased after 60 min. Continuous infusion caused minimal to moderate abdominal cramping within 2 min and prompted defecation and urination within 5 min. Three became nauseated and three had occasional premature artrial contractions. Systolic pressure increased transiently during the first 5 min from 121-142 mm Hg. Brachycardia occurred within 5 min and persisted for 60 min. Average portal pressure decreased from 365 to 280, 269, and 261 mm saline at 5, 30, and 60 min, resp. Average cardiac output decreased from 6.1 liters/min to 4.8 liters/min at 5 min, but after this, values rose to a less than significant output reduction. Portal vein reduction pressures at 15, 30, 45, and 60 min were significantly lower after infusion than after bolus injection. It is concluded that infusion causes significantly greater reduction of portal pressure, less discomfort, and less reduction in cardiac output than bolus injection.

4919 THE EFFECT OF DIURETIC TREATMENT ON RED CELL AND PLASMA SODIUM CONCENTRATION IN PATIENTS WITH HEPATIC CIRRHOSIS AND ASCITES. *(E.)* Afifi, F. (INSERM, Beaujon Hosp., Clichy, France). *Biomedicine* 23(2):68-72, 1975.

The sodium content of RBC and plasma in 10 patients with hepatic cirrhosis and ascites was measured before, during, and after diuretic treatment. The results were compared with findings in 37 normal subjects and 42 untreated cirrhotic patients with ascites. Before diuretic treatment the mean RBC sodium content in the 10 patients with ascites was 9.95 mEq/kg; expressed as mEq/kg dry weight and mEq/kg RBC water, the sodium content was 27.15 and 15.02, resp. During diuretic treatment, the mean RBC sodium content decreased significantly to 6.27 mEq/kg, 18.85 mEq/kg dry weight, and 10.15 mEq/kg RBC water. The mean pretreatment plasma sodium concentration was 135.95 mEq/kg, which significantly decreased during treatment to 129 mEq/kg. After cessation of diuretic treatment and the disappearance of ascites, RBC and plasma sodium levels returned to normal. *In vitro* ^{22}Na exchange between plasma and RBC of cirrhotic patients with ascites remained unmodified during diuretic treatment. These results indicate that RBC in patients with cirrhosis complicated by ascites are a parameter of intracellular sodium retention. Their increased sodium content is diminished by diuretic treatment.

4920 ADDITIONAL DATA ON HEPATIC FUNCTION TESTS IN CYSTIC FIBROSIS. *(E.)* Feigelson, J.; Pecau, Y.; Cathelineau, L.; Navarro, J. (Trousseau Hosp., Paris, France). *Acta Paediatr. Scand.* 64(2): 337-344, 1975.

Over a 3-yr period, various liver function tests were performed on 50 patients (20 men and 30 women, aged 1-26 yr) with cystic fibrosis, of whom nine had multilobular cirrhosis. Tests indicating cytolysis, cholestasis, and cellular insufficiency were carried out together with measurements of serum prothrombin and immunoglobulins. Test results were generally abnormal in the patients with cirrhosis. Two distinct biochemical types of cirrhosis were distinguished, one clearly cholestatic and the other a more cellular type. The first type was characterized by elevated γ-glutamyl transpeptidase levels, significant cytolysis with raised ornithine transcarbamylase and B_{12} levels, normal IgA, and normal or high transferrin levels giving an IgA:transferrin ratio of less than 1.0. The second type of cirrhosis was characterized by consistently high IgA levels with normal or low transferrin levels giving an IgA:transferrin ratio greater than 1.9. Of the noncirrhotic patients, 50% showed a temporary increase of cytolysis (elevated ornithine transcarbamylase and B_{12} levels) and cholestasis (elevated leucine aminopeptidase). Three of the 50 patients, including one with cirrhosis, developed viral hepatitis. In those without cirrhosis, all tests returned to normal and remained so for more than 2 yr. It is concluded that hepatic disfunction remains merely latent in cystic fibrosis.

4921 AN ATYPICAL CYTOPLASMIC ANTIBODY IN CHRONIC LIVER DISEASES. DETECTION BY INDIRECT IMMUNE FLUORESCENCE. *(Ger.)* Storch, W. (Med. Clin., Karl-Marx Univ. Leipzig, Germany). *Z. Inn. Med.* 29 (22):940-942, 1974.

Sera from 400 patients with chronic liver diseases (cirrhosis, chronic aggressive hepatitis), and from 400 normal subjects were tested for an atypical cytoplasmic antibody by indirect immune fluorescence, using rat kidney slices as an antigenic substrate for incubation. Atypical cytoplasmic antibody was found in 12 patients with chronic liver diseases, in one normal subject, and titers over 1:400 were found in four patients without liver disease. No sex-specific differences in the occurrence were established. The occurrence of the antibody was highest in patients with liver cirrhosis. Australia antigen was usually absent. There was no correlation between the occurrence of the atypical cytoplasmic antibody and the seriousness of the disease. Fluorescence exclusively of the proximal tubular epithelium was found. The typical pattern of the fluorescence clearly differed from those observed in the presence of other antibodies. The antibody is not specific of the species, and belongs to the IgG fraction. A single absorption on liver mitochondria and microsomes did not suppress the fluorescence.

4922 HEPATIC ARTERIES AND ARTERIAL CIRCULATION IN LIVER CIRRHOSIS. *(E.)* Takahashi, T.; Tezuka, F. (Tohoku Univ. Sch. Med., Sendai, Japan). *Tohoku J. Exp. Med.* 113(2):113-128, 1974.

Hepatic arterial circulation in normal and cirrhotic livers was analyzed by morphometrical treatment of the arterial system. Autopsy materials obtained from 32 cases of liver cirrhosis, three cases of Banti's syndrome, and 98 control cases were used. The cirrhotic group included postnecrotic and portal annular cirrhosis; biliary cirrhosis and cirrhosis with primary hepatic carcinoma were excluded. Arterial blood flow of the liver was estimated from the radius R_t of the proper hepatic arteries. The arterial flow Q was calculated from the equation $Q = q \cdot R_t^n$, where q and n are the organ-independent constants of the arterial system. The mean arterial flow Q in cirrhotic livers was significantly larger than in normal livers, and there was a striking individual difference in Q in cirrhotic livers. Arterial flow Q was closely correlated with the volume of interstitial tissue, but not with the volume of parenchymal tissue, in cirrhotic livers. In Banti's syndrome, the estimated hepatic arterial flow was within the normal range. It is concluded that the increased supply of arterial blood in liver cirrhosis was due solely to abundant intrahepatic shunts. Compensation of decreased portal flow by increased arterial supply was improbable.

4923 PLASMA AND RED BLOOD CELL PHOSPHOLIPIDS IN CHRONIC LIVER DISEASES. *(E.)* Cantoni, L.; Curri, S. B.; Andreuzzi, P.; Rocchetti, P. (Hosp. Maggiore Ca' Granda, Milan, Italy). *Clin. Chim. Acta* 60(3):405-408, 1975.

Total phospholipid levels and levels of phosphatidylcholine, lysophosphatidylcholine, phosphatidylethanolamine and phosphatidylserine, and sphingomyelin were determined in the plasma and RBC of 58 patients with chronic liver disease and 12 controls by quantitative extraction and thin-layer chromatography. The liver disease in 12 patients with cirrhosis was compensated, in 41 decompensated, the remainder having chronic aggressive hepatitis. Total phospholipid levels were significantly reduced in both the plasma and RBC of the patients with chronic liver disease, as compared with controls. Plasma sphingomyelein was significantly decreased in liver disease, while RBC showed a marked increase in lysophosphatidylcholine and a significant decrease in phosphatidylethanolamine and phosphatidylserine. It is suggested that in chronic liver disease, RBC lipid disturbances follow more closely those of the hepatocyte than those in plasma.

4924 ANTIBODY TITRE CHANGES AND SKIN REACTIVITY IN PATIENTS WITH LIVER CIRRHOSIS UNDERGOING PORTOCAVAL SHUNT OPERATION. *(E.)* Johansen, K. S.; Johansen, T. S.; Leerhoy, J. (State Serum Inst., Copenhagen, Denmark). *Acta Med. Scand.* 197(3):225-228, 1975.

Antibody titers to common antigens, and cell mediated immunity, were studied in cirrhotic patients undergoing portocaval shunts. Sera were collected from 10 patients with alcoholic and post-necrotic liver cirrhosis, and examined for HI antibodies to rubella and vaccinia, and CF antibody to cytomegalovirus. Normal blood donors (21) served as controls. Antistreptolysin O, antistreptococcal hyaluronidase, diptheria toxoid, *Candida* precipitin, syphilis reactions, *Salmonella typhi* O and H and *S. paratyphi* O and H were also determined. Skin tests were performed with *Candida albicans* extract, diptheria toxoid B antigen, streptokinase and tuberculin. Eight patients undergoing cholecystectomy served as controls for the skin tests, and for antibody titers to diptheria toxoid and *Candida albicans precipitins*. The rubella (7/10) and vaccinia (8/10) HI antibodies, diptheria (6/10) antitoxin, and antistreptolysin O (3/10) titers were significantly higher in cirrhotics than in controls (5/21, 2/13, 0/8, and 0/21, resp.). Total number of elevated antibody titers was 36 of 140 as opposed to 9 of 194 in the controls. About one month after the portocaval shunt, eight of the 10 patients had a positive titer index and none was negative. In one patient after surgery, rubella and vaccinia titers jumped from 20 to 160 and from 32 to 256, resp. The skin test reactions to the four antigens used were lower in the cirrhotics than in the controls, though significantly only with the diphtheria toxoid and streptokinase. After portocaval shunt, mean antibody titers increased with a concomitant decrease in skin test reactions, while there were no titer changes and normal indurational increases after cholecystectomy. It is concluded that elevated antibody titers to many common bacterial, fungal, and viral antigens are found in cirrhotic patients.

4925 THE ROLE OF IMMUNOLOGIC FACTORS IN THE PATHOGENESIS OF CHRONIC ACTIVE HEPATITIS. *(Pol.)* Bergiel, A. (Med. Acad., Lodz, Poland). *Przegl. Epidemiol.* 28(2):131-137, 1974.

Immunologic factors in progressive active hepatitis, primary biliary cirrhosis and cryptogenic cirrhosis are reviewed. Progressive hepatic diseases are frequently considered to be autoimmune diseases because of the absence of definite cause, more frequent occurrence among young women, chronic course with exacerbations, familial occurrence associated with other autoallergic diseases, hypergammaglobulinemia, high level of immunoglobulins, presence of autoantibodies in serum, presence of LE factor, lymphocytic infiltrations and positive response to treatment with immunosuppressive and glycocorticoid drugs. The role of T and B lymphocytes in the production of autoantibodies is discussed and stressed that both humoral and cell mediated immunity have to be considered in chronic liver diesease. Antibodies to smooth muscle have been detected in 39-50% of patients with progressive active hepatitis and in 50% of primary biliary cirrhosis; antimitochondrial antibodies in 25-30% and 83-93%, resp; antinuclear antibodies in 15-26% and 25%, resp. The role of Australia antigen (HB$_s$Ag) or its complexes in the pathogenesis of progressive hepatitis has not been elucidated but HB$_s$Ag-positive cases frequently have a different course and seem to have a better prognosis. "Mediolan" antigen, a lipoprotein, has been detected in serum when liver damage is present. It has been detected in 38% of patients with biliary cirrhosis, 26% of aggressive hepatitis and 30% of cryptogenic cirrhosis. Both HB$_s$Ag and "Mediolan" antigen show a negative correlation to other autoimmune factors such as antinuclear and anti-smooth muscle antibody levels and show no correlation to antimitochondrial antibodies. The role of humoral immunity and toxicity of circulating autoantibodies has not been established and their detection has only diagnostic significance in chronic liver diseases. Cell mediated immunity, on the other hand, seems to be important in the pathogenesis of these diseases. It is hypothesized that the T lymphocytes of subjects with normal cellular immunity can become sensitized to HB$_s$Ag antigen and attack liver cells containing HB$_s$Ag. Subjects with decreased cellular immunity become HB$_s$Ag carriers and show only slight liver damage.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

4940 A TEST FOR PATENCY OF THE CYSTIC DUCT IN ACUTE CHOLECYSTITIS. *(E.)* Eikman, E. A.; Cameron, J. L.; Colman, M.; Natarajan, T. K.; Dugal, P.; Wagner, Jr., H. N. (Johns Hopkins Med. Inst., Baltimore, Md.). *Ann. Intern. Med.* 82(3):318-322, 1975.

A radioactive tracer procedure was used to evaluate the patency of the cystic duct in 39 patients with acute abdominal pain. The gallbladder is first stimulated to empty by i.v. injection of chloecystokinin (75 Ivy dog U). After 30 min, either ^{125}I-rose bengal (150 μCi) or ^{99m}Tc dihydrothioctic acid (2 mCi) are injected and accumulation of radioactivity in the liver and gallbladder regions is monitored by external gamma emission imaging. Diagnostically significant images were recorded between 60-90 min after injection of tracer. Ten patients who subsequently proved to have acute cholecystitis failed to accumulate gallbladder radioactivity. The remaining 29 patients with a variety of other diseases all showed visualization of the gallbladder. There were no significant side effects or complications of the procedure, and it is concluded that this technique may be a useful adjunct to the clinical and roentgenographic evaluation of patients with acute abdominal pain.

4941 BILIARY LIPID OUTPUT DURING THREE MEALS AND AN OVERNIGHT FAST. I. RELATIONSHIP TO BILE ACID POOL SIZE AND CHOLESTEROL SATURATION OF BILE IN GALLSTONE AND CONTROL SUBJECTS. *(E.)* Northfield, T. C.; Hofmann, A. F. (Mayo Clin., Rochester, Minn.). *Gut* 16(1):1-17, 1975.

Using a duodenal perfusion technique, the biliary output of bile acids, phospholipid, and cholesterol was measured hourly during 3 meals and an overnight fast in 7 white patients (3 men and 4 women, aged 42-69 yr) with radiolucent gallstones in a functioning gallbladder, and in 7 healthy controls without gallstones, closely matched for age, sex, and weight. Before the perfusion, bile acid kinetics were defined by an isotope dilution procedure, and the biliary lipid composition of fasting gallbladder bile was determined. Total daily biliary lipid output was similar in gallstone and control subjects, and was unrelated to cholesterol saturation of fasting gallbladder bile and to bile acid pool size. There was an inverse relation between the size and recycling frequency of the bile acid pool, so that secretion rate and hepatic return of bile acids remained constant, despite a wide range of pool sizes. The finding of a normal bile acid synthesis rate in subjects with a small pool size therefore indicated normal feedback regulation of bile acid synthesis. Hourly measurements of biliary lipid output showed a linear relation between bile acid and cholesterol output, with a similar regression line for gallstone and control subjects, but a non-linear relation between bile acid and phospholipid output. Consequently, samples from all subjects were consistently supersaturated with cholesterol at low bile acid outputs, especially during overnight fasting, but not at high bile acid outputs. These findings indicate that hepatic secretion of bile supersaturated with cholesterol is physiological in man at low bile acid outputs, that bile acid pool size is probably determined in part by its recycling frequency, and that cholesterol cholelithiasis in some whites may be due to an underlying extra-hepatic abnormality.

4942 EFFECT OF PHENOBARBITAL IN A CASE OF EXTRAHEPATIC CHOLESTASIS. *(E.)* Metreau, J. M.; Bismuth, H.; Franco, D.; Dhumeaux, D. (Hosp. Henri Mondor, Creteil, France). *Gastroenterology* 68(3): 567-571, 1975.

Treatment of an extrahepatic biliary obstruction in a 44-yr-old woman is described. The woman presented with jaundice and pruritus. For 2 weeks she had complained of nausea, headache, and asthenia and for 10 days had had moderate fever, pruritus, and vomiting. In the preceeding 6-month period she had taken at least 15 different drugs, including opipranol, indomethacin, diazepam, and sulfamethoxydiazine. Probable cholestatic hepatitis was diagnosed. She was discharged on cholestyramine alone, which was stopped after 2 days due to diarrhea. One month later she returned with icterus and pruritus: serum bilirubin was 10.0 mg/100 ml; alkaline phosphatase, 270 IU. Phenobarbital administration was started and slowly increased to 200 mg/day. After 1 week, pruritus and serum bilirubin levels diminished. After 1 month pruritis was reduced, serum bilirubin was 7.0 mg/100 ml. However, the serum alkaline phosphatase remained high at 240 IU. Phenobarbital was stopped. Two months later she suffered a progressive relapse of pruritus and jaundice. Serum bilirubin was 22.0 mg/100 ml; alkaline phosphatase, 660 IU; and total bile acids, 160 μg/ml. Biopsy revealed marked cholestasis and portal sclerosis containing numerous inflammatory cells with few polymorphonuclear leukocytes. Phenobarbital again lowered the pruritus and bilirubinemia and reduced bile acids to 51 μg/ml, but the alkaline phosphatase progressively increased to 1120 IU. Adenocarcinoma was diagnosed and a cephalic pancreatic duodenectomy (Whipple procedure) was sucessfully performed. The phenobarbital-induced decrease in pruritus, serum bilirubin, and bile acids suggests that this drug may be effective in extrahepatic cholestasis, possibly causing enhanced biliary secretion of cholephilic organic anions. It is noted that caution must be taken before interpreting this effect of phenobarbital as relecting the intrahepatic origin of a cholestasis.

4943 ACUTE EMPHYSEMATOUS CHOLECYSTITIS. *(E.)* Abengowe, C. U.; McManamon, P. J. M. (Gen. Hosp., St. John's, Canada). *Can. Med. Assoc. J.* 111 (10):1112-1113, 1974.

A 74-yr-old North American diabetic man with Indian ancestry was hospitalized with a 3-day history of acute, steady, progressive, right upper quadrant abdominal pain associated with nausea and vomiting for 48 hr. Laboratory findings were as follows: leukocyte count 15,000/mm^3, LDH 225 mU/ml, SGOT 76 mU/ml, total bilirubin 1.5 mg/deciliter, serum amylase 40 U/ml, urinary amylase 16 U/ml, fasting blood sugar 197 mg/deciliter, Hb 15 g/deciliter, Hct. 46%, and erythrocyte sedimentation rate 83 mm/hr. A plain film of the abdomen showed an ovoid gas shadow measuring 9 x 5 cm and situated high in the right hypochondrium, which was interpreted as representing gas in the gallbladder. A second plain film made 24 hr later showed the gas involving the gallbladder wall as well. A diagnosis of acute emphysematous cholecystitis was made and a gangrenous distended gallbladder removed at operation. *Clostridium perfringens* was cultured from the gallbladder contents and wall. A review of the literature indicated that acute emphysematous Cholecystitis is more prevalent among male diabetics. Its clinical and laboratory manifestations are similar to those of ordinary acute cholecystitis; diagnosis cannot be made preoperatively without radiologic studies. If acute emphysematous cholecystitis is suspected, it is suggested that intensive antimicrobial therapy and fluid and electrolyte replacement be given prior to early surgical intervention.

4944 EMPTYING OF THE HUMAN GALLBLADDER AND PREDISPOSITION TO GALLSTONE FORMATION. *(E.)* van der Linden, W. (Cent. Hosp., Ostersund, Sweden). *Tijdschr. Gastroenterol.* 17(2):121-128, 1974.

Oral cholecystography performed in patients in whom the gallbladder was visualized without revealing the presence of stones were repeated 30 min after the ingestion of a meal consisting of two egg yolks with sugar to assess the rate of gallbladder emptying. The films were reviewed to estimate gallbladder volume. The patients were separated into two groups, those with a sluggish and those with a vigorous postprandial contraction. In the sluggishly contracting group far more patients were under than over 45 yr of age. In the strong contraction group, more patients were over than under 45 yr of age. Women predominated in the sluggish group while in the other group there was no sex differentiation. During the 13-14 yr between the cholecystographies and this follow-up study, two men in the fibrous contracting group had been operated on for duodenal ulcer, four patients had been appendectomized, one cholecystectomized and two subjected to gynecological operations. In the sluggishly contracting group there were no gastric operations, four appendectomies, five cholecystectomies, one herniotomy and two gynecological operations. In 12 of the 35 patients who at follow-up could be traced to the sluggish group, cholecystography was repeated and signs of gallstone disease were present in seven. In the fast contraction group, x-ray examination was repeated in nine of the 36 patients who could be traced and gallstone disease was diagnosed in only one. In the sluggishly contracting group, gallstones were found significantly more often when cholecystography was performed some years later. The results of this study show that a sluggish contraction of the gallbladder after an egg yolk meal occurs particularly often in pre-menopausal women. The results further indicate that patients with such gallbladders are especially prone to develop gallstones in later life.

4945 THE CHOLECYSTOKININ TEST: AN ASSESSMENT.

(E.) Reid, D. R. K.; Rogers, I. M.; Calder, J. F. (R. Infirm., Glasgow, Scotland). *Br. J. Surg.* 62(4):317-319, 1975.

The significance of the cholecystokinin (CCK) test was investigated in 13 patients thought to have x-ray negative gallbladder pain. Duration of the symptoms ranged from 8 months to 10 yr. The patients were told they would be having a cholecystogram (all had one previously) during which they would receive an injection; they were not told the injection might provoke pain. Prone, prone-oblique, and erect films were taken 14 hr after ingestion of six iopanoic acid tablets. Cholecystokinin-pancreozymin was injected over a 1-min period and further films were taken after 2, 4, 6, 8, and 20 min. The injection of 1.5 Ivy U/kg CCK was done into the tubing of an i.v. saline infusion set-up behind the patient so that she was not aware of the moment of injection. The test was considered positive if typical pain was experienced within 10 min. In nine patients, surgery had been indicated clinically. Of these, four were test positive, four test negative, and one was equivocal. Of the four positive reactors, three were relieved by surgery; the fourth had a large functional overlay. Of the four negative reactors, three were relieved by surgery. The remaining patient may have had a small residual stone in the common bile duct after surgery. The patient with equivocal test results was relieved by surgery. Of the four non-operated patients, all were test negative. One was later given a truncal vagotomy and pyloroplasty for duodenal ulcer, but the pains continued. A 14th patient, not included in the series, presented with apparent biliary colic two yr after cholecystectomy gave a positive CCK test. Only three of the patients showed good gallbladder contraction in response to cholecystokinin. It is concluded that a positive test would indicate cholecystectomy while a negative test does not absolve the gallbladder as the source of pain.

4946 ROUX-EN-Y HEPATICJEJUNOSTOMY: A REAPPRAISAL OF ITS INDICATIONS AND RESULTS. *(E.)*

Stefanini, P.; Carboni, M.; Patrassi, N.; Basoli, A.; De Bernardinis, G.; Negro, P. (Univ. Rome Med. Sch., Italy). *Ann. Surg.* 181(2):213-219, 1975.

A critical evaluation was made of 131 patients (51 men and 80 women, aged 31-73 yr) submitted to choledocho- or hepaticojejunostomy. The main indications for hepaticojejunostomy were iatrogenic strictures of the common bile duct (60 patients), and choledocholithiasis with markedly dilated duct (41). The overall mortality rate was 4%, principally due to renal hepatic failure, bile peritonitis and bleeding. The complications following hepaticojejunostomy included only one case of biliary fistula which required reoperation. The long-term results of 80 patients available for a follow-up study were as follows: 63 patients (78.7%) were symptom-free at 2-13 yr after surgery; eight patients had brief episodes of cholangitis which responded to antibiotic and corticosteroid treatment; nine patients required reoperation for stricture of anastomosis. These overall results offer a strong argument for hepaticojejunostomy which, compared with choledochoduodenostomy, avoids the hazards of the so-called sump syndrome and of the reflux of enteric contents into the common bile duct. An increased incidence of peptic ulcer disease in the patients submitted to hepaticojejunostomy was not observed. In very high strictures and in reinterventions, anastomosis between left hepatic duct and Roux-en-Y jejunal limb was carried out. The results achieved with this technique in 26 patients were about the same following hepaticojejunostomy. Thus it is concluded that hepaticojejunostomy, as opposed to choledochoduodenostomy, be used in treating obstructions of proximal as well as distal common bile duct. Additionally, hepaticojejunostomy is advised as the most appropriate procedure in patients with choledocholithiasis and markedly dilated duct.

4947 ADENOCARCINOMA OF THE BILE DUCTS. RELATIONSHIP OF ANATOMIC LOCATION TO CLINICAL FEATURES.

(E.) Ingis, D. A.; Farmer, R. G. (Cleveland Clin., Ohio). *Am. J. Dig. Dis.* 20(3):253-261, 1975.

Case histories of 23 patients with adenocarcinoma of the bile ducts presenting over a 14-yr period were reviewed and a comparison made between carcinoma in the hepatic duct system and carcinomas in the common bile duct. In 14 patients (10 women and four men, aged 38-81 yr) the carcinoma arose in the hepatic duct system. In nine (seven women and two men, aged 44-82 yr) the carcinoma arose in the common bile duct. It was found that age, sex, presenting symptoms, physical examination, and laboratory findings were similar regardless of the location of the carcinoma. Moreover, the location did not influence whether the correct diagnosis was made at the initial operation as carcinomas in both locations, although present, were not found by surgeons at the time of the original operation. Percutaneous cholangiography, operative cholangiography, and endoscopic retrograde cholangiopancreatography were successful in making the diagnosis in both locations. Other preoperative tests, while showing obstructive jaundice at times, did not aid the surgeon prior to operative intervention. The tumors differed in pathology: hepatic duct carcinomas were often scirrhous; the more distal carcinomas were adenocarcinomas of varied grades. The location influenced the type of surgery. Resection was more common in the distal common bile duct cases. The average survival was less than 2 yr for both locations. In eight hepatic duct carcinoma patients 5-fluorouracil was given p.o. or i.v. weekly following surgery. In two patients cobalt therapy consisting of 2500 - 5000 rads locally to the area of the carcinoma was followed by 5-fluorouracil therapy. In one case, cobalt therapy of 2400 rads alone was given. These measures did not appear to increase the survival of these patients. In the patients with carcinoma of the common bile duct, only one received 5-fluorouracil and he lived only 2 months. Radiation was not used in any of these cases. In view of the poor prognosis for patients with these carcinomas, it is urged that attention be focused on means of earlier diagnosis.

4948 PERCUTANEOUS LIVER BIOPSY IN PATIENTS WITH LARGE BILE DUCT OBSTRUCTION. *(E.)* Morris, J. S.; Gallo, G. A.; Scheuer, P. J.; Sherlock, S. (R. Free Hosp., London, England). *Gastroenterology* 68(4):750-754, 1975.

The safety and diagnostic value of percutaneous liver biopsy were reviewed in 125 patients with large bile duct obstruction. Prior to biopsy, none had palpable gallbladder or suspected cholangitis. In two cases a Vim-Silverman needle was used; in the remainder, a Menghini needle. All patients received 10 mg vitamin K i.m. for 2 days before biopsy. For 24 hr after biopsy, patients were kept in bed, and pulse, temperature and blood pressure were recorded at regular intervals. The biopsy was considered to be diagnostic or suggestive of large bile duct obstruction when most of the following were found: central cholestasis; duct replication; expansion and edema of portal tracts with leukocyte infiltration; and bile infarction. Each patient's record was examined for initial clinical diagnosis, discharge or autopsy diagnosis, complications of liver biopsy, and operative findings. Serum bilirubin levels ranged from 5 to over 20 mg/100 ml, and in 42% jaundice had been present for over 6 months. Percutaneous cholangiography was attempted in 47 patients, and was successful in 38. Of the 125 patients, eight developed complications: biliary peritonitis (one); severe pain in the upper right abdomen (three); pyrexia and chills (two); pleural effusion and blood-stained ascites (one each). There was no apparent relation between development of complications and the depth of jaundice or the anatomical abnormality. Needle biopsy failed in two patients. In 103 cases, the initial biopsy showed changes compatible with large duct obstruction, in 16 the sole abnormality was cholestasis, and in six, results were unhelpful or misleading. Of 38 patients in whom the ducts were successfully punctured, 32 showed changes associated with large duct obstruction, and six cholestasis. It is concluded that needle biopsy is useful and safe to perform in patients with large duct obstruction; however, a careful prebiopsy work-up and close observation for 24 hr after biopsy are essential.

4949 CHOLECYSTECTOMY PEER REVIEW: MEASUREMENT OF FOUR VARIABLES. *(E.)* Mitchell, J. H.; Hardacre, J. M.; Wenzel, F. J.; Lohrenz, F. N. (Marshfield Clin., Wisconsin). *Med. Care* 13(5):409-416, 1975.

Patients undergoing uncomplicated cholecystectomy (222) were evaluated by both process and outcome methods, and their satisfaction and duration of postoperative stay were measured. Criteria for process analysis were: indications for admission; laboratory tests; length of postoperative stay; indications for discharge; and other components for a comprehensive medical record. Of the 222, 80 at random were used as the basis for this analysis. Outcome was divided into five types: asymptomatic and back-to-normal activities; symptomatic and back-to-normal activities; not back-to-work or normal activities; bedridden; and dead. Information was gathered from the medical records and patients answered a questionnaire to determine outcome status and satisfaction. After the analyses were completed, the patients were divided into those with bile duct exploration and those without. Each group was subdivided according to surgeon, and mean postoperative stay for each surgeon's patients calculated for each variable. The major omission found by process review was the absence of preoperative serum amylase test in eight of 18 patients with acute cholecystitis. In one instance there was no record of urinalysis or hematocrit. All had abnormal gallbladders documented by pathological reports. Outcome analysis results were within predicted expectations in four categories. In the symptomatic back-to-work group, however, there was 31% of the patients, in contrast to the predicted 13%. There were no statistical differences in length of postoperative stay among the surgeons of the bile duct exploration group. In contrast, the group given no such exploration showed a marked difference in stay among their surgeons. One surgeon kept patients an average of two days longer than another in the group. Of all the patients, 95% were satisfied with their care and 90% felt the length of their postoperative stay was appropriate. It is concluded that process outcome and patient satisfaction were satisfactory, and length of postoperative stay may be shortened.

4950 BILE ACID PATTERN OF GALLBLADDER AND HEPATIC BILE IN PATIENTS WITH AND WITHOUT CHOLESTEROL GALLSTONES. *(E.)* Arnesjo, B.; Bodvall, B.; Stahl, E. (Dep. Surg., Univ. Lund, Sweden). *Acta Chir. Scand.* 141(2):135-138, 1975.

Gallbladder bile acid pattern was compared in 18 patients with cholelithiasis and 13 with duodenal ulcer disease. Both gallbladder and hepatic bile specimens were taken after an overnight fast during cholecystectomy or selective proximal vagotomy.

Bile acids were immediately extracted with methanol acetone and separated by thin layer chromatography. Molar concentrations were determined, as well as the ratios of molar concentrations of glycine:taurine conjugated acids, trihydroxy:dihydroxy acids, cholate:deoxycholate, cholate:chenodeoxycholate, cholate plus deoxycholate:chenodeoxycholate and chenodeoxycholate:deoxycholate. In each case, hepatic bile molar ratios were divided by gallbladder bile molar ratios. The individual hepatic to gallbladder bile acid molar ratios were then compared with those of the control duodenal ulcer patients. The total bile acid concentration of the gallbladder bile in the controls (164.7) was higher than that of the gallstone group (122.9). There were no differences between the two groups in bile acid patterns, excepting a lower trihydroxy:dihydroxy ratio in the gallstone group. Individual hepatic to gallbladder relative molar ratios in the gallstone group had elevated trihydroxy:dihydroxy (1.35) and cholate:deoxycholate (1.47) ratios. It is concluded that gallbladder bile from gallstone patients has a diminished trihydroxy:dihydroxy molar ratio.

4951 GALL-STONES AND ORAL CONTRACEPTIVES. *(E.)* Howat, J. M. T.; Jones, C. B.; Schofield, P. F. (Park Hosp., Manchester, England). *J. Int. Med. Res.* 3(2):59-62, 1975.

Female patients (100) were studied to determine whether oral contraceptives increased risk of gallstone formation. Of these, 50 presented for surgery with gallstones, and 50 were controls admitted for minor surgery or as a result of trauma. A record was kept of those who had taken oral contraceptives for over six months at any time prior to admission. The number of pregnancies and miscarriages were recorded so the two groups could be matched for parity. Of the 50 gallstone patients, 35 (70%) had used contraceptives for at least six months, as compared to 14 (28%) of the controls, a highly significant difference. Parity and marital status did not differ between the groups. It is concluded that there is a markedly higher oral contraceptive use in gallstone patients than in normal controls.

4952 STUDIES ON BILE SALT DECONJUGATION FOLLOWING SMALL BOWEL BYPASS PROCEDURES. *(E.)* Wise, L.; Margraf, H.; Stein, T. (Washington Univ. Sch. Med., St. Louis, Mo.). *Ann. Surg.* 181(4):397-401, 1975.

The amount of bile salt deconjugation and malabsorption following small bowel bypass was studied, and the role of the glycine-1-^{14}C-cholic acid (^{14}C-GCA) test in evaluating the intestinal adaptive response and bypass adequacy was assessed. Patients (26) with morbid obesity had 35 cm of proximal jejunum anastomosed end-to-end to 10 cm of terminal ileum. Glycine-1-^{14}C-cholate was given p.o. and the specific activity of the expired $^{14}CO_2$ was determined to serve as an index of bacterial deconjugation. The ^{14}C content of 48-hr stool specimens following ingestion of the label served as a malabsorption index. These studies were performed a week prior to surgery and also 3-4 days, 8-10 days, and 5-11 months after surgery. During the postoperative period, $^{14}CO_2$ excretion was no higher than 0.1% dose/mM CO_2/kg, even after 6 hr. In the immediate postoperative period (during antibiotic therapy) there was no measurable $^{14}CO_2$ excretion, but after 8-10 days there was a significant increase. High excretion started within 2 hr (0.51 x 0.12) and persisted for about 8 hr. At 6 hr the increase was 20%. After 5-10 months there was a significant 10% increase in early CO_2 output (0.37 x 0.05 at 4 hr) for six hr. Mean ^{14}C respiratory loss during the first 6 hr was 2.2%, in the 8-10 day group 25.4%, and in the 5-11 month group 15.9%. The percentage of loss was increased significantly in both postoperative groups over the preoperative group and in the early as opposed to the late postoperative group. Mean fecal ^{14}C excretion was 6.6% of the preoperative dose, 50.9% in the early postoperative period, and 21.2% in the late postoperative period, indicating a decrease and compensatory increase in bile salt absorption. It is concluded that the ^{14}C-GCA test may be used to follow the adaptive response following bypass surgery.

4953 SCLEROSING CHOLANGITIS: SURGICAL SIGNIFICANCE. *(E.)* Grodsinsky, C.; Block, M. A.; Brush, B. E. (Henry Ford Hosp., Detroit, Mich.). *Henry Ford Hosp. Med. J.* 22(4):211-216, 1974.

A review is presented of six cases of possible sclerosing cholangitis. Criteria for inclusion of a case were: absence of previous biliary tract surgery and of gallstones; diffuse involvement of the extrahepatic ducts; and exclusion of cholangiocarcinoma. All had been treated for extrahepatic lesions; in two the intraoperative findings were similar. Absence of postmortem examinations made confirmation of intraoperative diagnosis impossible. At least three patterns of anatomic involvement were observed. The first, the segmental sclerosing type, results in recurrent bouts of cholangitis which may be relieved by surgical bypass of the obstruction. Stenosis is limited to a segment, usually distal, of the extrahepatic ducts. Prognosis is good. The diffuse sclerosing type, in contrast, is usually associated with chronic ulcerative colitis, and involves the entire biliary tract, intra- and extrahepatic. The third type, primary fibrosing pericholedochitis, involves the extrahepatic tract and is difficult to distinguish from other lesions causing chronic inflammation in this region. Subsequent clinical course after surgery must be reviewed to establish diagnosis. It is suggested that all possible mechanical methods of relief through surgery should be attempted, and steroids administered as an alternative where the first is ineffective or impossible.

4954 BILIOBILIARY FISTULA. A TRAP IN THE SURGERY OF CHOLELITHIASIS. *(E.)* Corlette, M. B.; Bismuth, H. (Paul Brousse Hosp., Villejuif, France). *Arch. Surg.* 110(4):377-383, 1975.

Case studies are presented for 24 patients (5 men and 19 women, average age 60.2 yr) treated for calculous biliobiliary fistula. Jaundice was the most common symptom, usually sudden in onset and associated with pain. The duration of biliary symptoms ranged from 15 days to 20 yr. Marked weight loss occurred in six. Bilirubin ranged from 2.5-14.8 mg/100 ml; alkaline phosphatase, 35-600 IU. At operation a constant and important finding was marked adhesions in the right upper quadrant fusing the adjacent organs into a chronic inflammatory mass. The gallbladder was shrunken and thickly scarred in all but two patients, in whom it was necrotic and removed in fragments. In no case was there a distinguishable line of demarcation between gallbladder and main bile duct, and the latter could not be readily dissected from the gallbaldder. In 18 cases the location in which an abnormal communication occurred between gallbaldder and main bile duct was between the Hartmann pouch or the ampulla of Vater and the hepatic duct. In six cases the gallbladder neck was continuous with the main bile duct, and a large direct communication existed between the gallbladder and the common duct in the trajectory of the cystic duct. A stone larger than 1.5 cm in diameter was found in 21 cases. In 11 cases a huge stone was astride the fistula, partly within the gallbladder and projecting into and obstructing the main bile duct. Treatment consisted of removal of stones and partial cholecystectomy down to the fistulized zone, leaving a remnant of gallbladder tissue about the abnormal communication. A T-tube was inserted through the fistula and the duct closed about it in 21 patients. In three cases an hepaticojejunostomy was performed. Postoperative complications included septis (two), partial transitory bile fistula, and self-limited episode of gastrointestinal tract bleeding (one each). One patient became jaundiced 4 months after closure of the fistula and at reexploration had developed a carcinoma obstructing the hepatic duct. It is emphasized that no attempt should be made to dissect the main bile duct from the gallbladder due to great danger to the duct. By opening the gallbladder peripherally and obtaining a cholangiogram, such an abnormal communication can be diagnosed. It is best treated by leaving a small collar of gallbladder tissue about the fistula and using this tissue to close the main duct over a T-tube.

4955 STUDIES IN CHOLESTASIS OF PREGNANCY. I. CLINICAL ASPECTS AND LIVER FUNCTION TESTS. *(E.)* Johnson, P.; Samsioe, G.; Gustafson, A. (Sahlgrenska Hosp., Univ. Goteberg, Sweden). *Acta Obstet. Gynecol. Scand.* 54(1):77-84, 1975.

Consecutive cases of pruritus in pregnancy (59) were investigated; 57 were without obvious dermatological causes and were further studied for clinical features related to the occurrence of lipoprotein X (LP-X) in serum and to liver function tests. The onset of pruritus due to cholestasis was during the third trimester in 65% of the patients. The occurrence of new cases was highest in the sixth and eighth months of pregnancy. Emesis was more common among patients with cholestatis (75%) than among controls (58%). Gallbladder disease was more frequent in pregnant women with pruritus than in controls. Food and drug idiosyncracy was more common in cholestasis of pregnancy and included difficulties with penicillins, sulfonamides, strawberries, fish, and oranges. There was no significant difference in age between cholestasis of pregnancy patients and controls. The time of delivery was normal in both groups. The amount of uterine bleeding during delivery was normal in each group, as was the patient distribution among A, B, O, and Rh blood groups. The newborn infant of the mother who had suffered from pruritus during pregnancy was not afflicted with a higher perinatal mortality nor was the incidence of immaturity and dysmaturity higher than in controls. Pregnant women with pruritus due to cholestasis showed wide ranges of values for liver function tests, serum bilirubin, alkaline phosphatase, SGOT and SGPT. In only three cases was the serum bilirubin elevated, while only a minor portion of the values of alkaline phosphatase were within normal limits. SGOT and SGPT followed a pattern similar to alkaline phosphatase, increasing in relation to the length of gestation. The cholestatic cause of the pruritus was verified in the 57 patients by the presence of LP-X in serum as determined by the immunological technique. LP-X was frequently present in serum together with normal alkaline phosphatase, SGOT, and SGPT and was particularly notable in cases in whom the onset of pruritus was in the second trimester. The finding of prolonged and severe emesis early in pregnancy suggests that the basic and possibly metabolic disturbance causing cholestasis is present throughout pregnancy, even though the onset of pruritus in cholestasis of pregnancy is most frequent in the last trimester. It is suggested that the modified immunological test for the detection of LP-X in serum may be a useful diagnostic tool in the diagnosis of cholestasis of pregnancy.

4956 A RARE CASE OF CYSTIC DILATATION OF THE MAIN BILE DUCT ("CHOLEDOCHOCELE"). *(It.)* Pelizzo, M. R.; Stella, G. D.; Masutti, A. (Inst. Surg, Pathol., Univ. Padua, Italy). *Chir. Ital.* 26(5): 488-494, 1974.

GENERAL

5013 AMPICILLIN-ASSOCIATED DIARRHEA--A PROSPECTIVE STUDY. *(E.)* Tedesco, F. J. (Washington Univ. Sch. Med., St. Louis, Missouri). *Am. J. Dig. Dis.* 20(4):295-297, 1975.

A prospective study of 200 consecutive patients (131 women and 69 men, aged 15-91 yr) given ampicillin for various reasons showed that bowel habits changed in 32 (16%) and that 9 of the 32 (4.5%) had diarrhea. The incidence of change in bowel habits increased with total dosage and the change occurred with equal frequency after p.o. and i.v. administration of ampicillin. Proctoscopic examination of 17 patients with changed bowel habits showed edema in all patients with more than 5 bowel movements/day and erythema in 1/2 the patients. However, no case of pseudomembrane colitis was found. A comparable study of 200 patients treated with clindamycin had revealed a 21% incidence of diarrhea and a 10% incidence of pseudomembrane colitis.

5014 IMMUNOFLUORESCENCE IN DUODENAL MUCOSA OF CHILDREN WITH ACUTE ENTERITIS DUE TO A NEW VIRUS. *(E.)* Davidson, G. P.; Goller, I.; Bishop, R. F.; Townely, R. R. W.; Holmes, I. H.; Ruck, B. J. (R. Child. Hosp., Melbourne, Australia). *J. Clin. Pathol.* 28(4):263-266, 1975.

Electron microscopy of duodenal mucosa from 8 children with acute nonbacterial enteritis had shown duovirus particles in epithelial cells. Indirect immunofluorescent techniques were applied to the same tissue and showed virus antigen localized in the cytoplasm of epithelial cells of the villi. Fluorescence occurred with fluorescein-labeled antisera to human IgM but not with similarly labeled antisera to IgG or IgA. Specific IgM antibody was present in sera from infected patients as early as 2 days after the onset of symptoms. Virus particles from different patients appeared to share a common antigen since the particles fluoresced when incubated with heterologus sera. These results support the belief that duovirus was the cause of acute enteritis in the children studied.

5015 GASTROINTESTINAL BLEEDING: TREATMENT WITH INTRA-ARTERIAL VASOPRESSIN. *(E.)* Geronilla, D. R.; Sampliner, J. E.; Lerner, A. (Mt. Sinai Hosp., Cleveland, Ohio). *Am. Surg.* 41(5):321-326, 1975.

The use of selective intra-arterial vasopressin in the treatment of 17 cases (12 male, five female) of gastrointestinal hemorrhage is discussed. Vasopressin was administered by continuous pump infusion through either the celiac or the superior mesenteric arteries. Of 17 patients, 16 had bleeding coming from above the ligament of Treitz and only one patient had lower gastrointestinal bleeding. Vasopressin was infused with a starting dose of 0.4 U/min for 20-30 min in the celiac artery, then reduced to 0.2 U/min. Superior mesenteric artery infusion was started with 0.2 U/min. Vasopressin was gradually tapered after cessation of bleeding and catheter removal was accomplished in less than 3 days. The treatment stopped the gastrointestinal hemorrhage in 13 of 17 patients (76.5%). No major complications occurred. Despite the early successes of this treatment, its therapeutic indications are still not fully established. It is suggested, however, that vasopressin has a use in stabilizing the condition of the bleeding patient, providing time for full diagnostic evaluation, and converting an emergency surgical procedure to an elective one.

5016 CHEMICALLY DEFINED DIET IN THE TREATMENT OF KWASHIORKOR. *(E.)* Habte, D.; Persson, B.; Sterky, G. (Dep. Pediatr., Haile Selassie I Univ., Addis Ababa, Ethiopia). *Acta Pediatr. Scand.* 64(2): 267-272, 1975.

A synthetic feeding mixture with an almost exclusively monomolecular composition was tested in children with kwashiorkor. Of 21 children, 13 received the synthetic food and eight received a standard diet with cow milk protein concentrate. Feeds were given every third hr at 100 mg/kg/day in the beginning, usually *via* nasogastric tube, for the first few days. Tea with sugar was given to all patients on the first day, half strength nutrient on the second day and full strength on the third day. Rectal temperature was taken before each feed and 1, 2, and 3 hr after. Venous blood was drawn on the second day of admission, every second day for the first week, and weekly thereafter, to be analyzed for blood urea nitrogen, glucose, and albumin. Hemoglobin was determined from capillary blood. There were six deaths, four in the synthetic and two in the standard-fed groups. Four were due to dehydration from diarrhea, one from hypoglycemia and one from congestive heart failure. The mortality corresponded to that of the in-patients of the hospital. The synthetic-fed group took the food from the bottle by the second or third day, showing rapid increase in appetite, while the standard-fed group had to be tube-fed for about a week. The synthetic-fed group improved more quickly than the standard-fed group, the groups taking 7.1 and 14.1 days, resp., to attain minimum weight. Subsequent weight gain was the same in both groups. Frequency of vomiting was significantly higher in the standard-fed group. There was a rise in rectal temperature in most of the patients, but was more pronounced and significant during the first half of the week in the synthetic-fed group. Albumin and blood urea nitrogen showed a progressive rise in both groups and became significant in the standard-fed group on day eight and the synthetic-fed group on day 15. There was also a significant increase in hemoglobin concentration during the first 3 weeks in the synthetic-fed group only. It is concluded that a completely chemically-defined diet can successfully reverse acute kwashiorkor, with minimum weight reached sooner and with less protein than the standard diet.

5017 IMPORTANCE OF MULTIPLE EPISODES OF HYPOXIA OR COLD STRESS ON THE DEVELOPMENT OF ENTEROCOLITIS IN AN ANIMAL MODEL. *(E.)* Barlow, B.; Santulli, T. V. (Coll. Physicians Surg., Columbia Univ., New York, N.Y.). *Surgery* 77(5):687-690, 1975.

The effects of cold stress or of the number of episodes of cold stress or hypoxia on the development of acute necrotizing enterocolitis was investigated in the rat. Split litters of newborn Sprague-Dawley rats were used for breast-fed and formula-fed groups for each experimental condition. Cold stress by refrigeration for 5 min at 7 C was administered once daily for 1, 2, or 3 days for some groups. Hypoxia by enclosure of the animals in a plastic bag for 3-5 min was administered once daily for 1, 2, 3, or 4 days to other groups. All rats were given an oral innoculum of *Klebsiella* bacteria at birth. Fecal and blood cultures and pathological examination of the gut were performed on all rats. Diseased rats were killed when in a terminal state, and healthy survivors when 7 days old. None of the breast-fed litter mates in the cold or hypoxia stressed groups showed any pathological changes. Stool cultures showed rare gram-negative colonies at 7 days. The formula-fed rats showed development of necrotizing enterocolitis in direct relation to the number of stress episodes. The disease occurred at 2-5 days of age in 60% after one, and 100% after two or more cold stress episodes. Hypoxia caused the disease in 20% after one stress, 60% after two, 80% after three, and 100% after four. Fecal and blood cultures all showed heavy *Klebsiella* growth. It is concluded that a critical amount of enteric ischemia, as caused by various forms of stress, is required to initiate enterocolitis, and that breast milk protects against the disease by control of bacterial growth.

5018 USE OF AN ORAL ELEMENTAL DIET IN INFANTS WITH SEVERE INTRACTABLE DIARRHEA. *(E.)* Sherman, J. O.; Hamly, C.; and Khachadurian, A. K. (Child. Mem. Hosp., Chicago, Ill.). *J. Pediatr.* 86(4):518-523, 1975.

The efficacy of an oral elemental diet, Vivonex, in the treatment of severe intractable diarrhea in 27 infants (1 day to 9 months of age) and the diet's effect on nitrogen balance, plasma amino acids, lipid metabolism and acid-base balance were studied. The oral elemental diet (an 18% solution) consisted of crystalline amino acids, glucose, electrolytes, and vitamins and was administered by continuous nasogastric drip. The etiology of the diarrhea was nonspecific in 23 cases and bacterial in four. Diarrhea was controlled in 24 of 27 patients on the elemental diet, and the mean weight gain was 28 g/day. The mean length of treatment was 24 days. Some of the infants received standard Vivonex and others received Vivonex high-nitrogen diet. Those fed the standard diet received the recommended level of amino acids, but their nitrogen retention and weight gain were less than optimum. Feeding the high-nitrogen formula (4.58 g/kg/day of amino acids) resulted in acceptable nitrogen retention and weight gain. The levels of individual plasma amino acids did not directly reflect the levels in the diet. Plasma triglyceride values remained within normal limits. SGPT was elevated in two patients after 13 days on the high-nitrogen diet and this may have indicated some transient liver toxicity. The higher levels of blood urea nitrogen in those receiving the high nitrogen diet probably reflected an excessive nitrogen intake. Although the oral elemental diet offers several advantages over total parenteral nutrition, the results suggest that an elemental diet specifically designed for use in infants should be developed. However, for patients with severe intractable diarrhea not responsive to conventional therapy, the presently available elemental diets represent a reasonable therapeutic alternative.

5019 AN APPLICATION OF SPECIAL ANALYSIS TO THE PROCESSING OF BIOELECTRIC VISCERAL SIGNALS. *(Fr.)* Tonkovic, S.; Penaud, J.; Thouvenot, J.; Mountafian, J. P. (Lab. Biomed. Electron., Fac. Electrotech., Zagreb, Yugoslavia). *Med. Biol. Eng.* 13(2):266-271, 1975.

Cutaneous abdominal electrodes were used to study overall bioelectric digestive activity in eight subjects, aged 20-25 yr. Two pairs of points symmetrically located on each side of the midline, one pair just below the rib cage and the other just above the pubis, were used for bipolar derivation of four signals. The sequential organization of the digestive motor process permits consideration of the signal as stationary within a defined interval. Therefore, the methods of spectral analysis may be applied to the values determined during the sequences of digestive activity. The power spectra produced by the eight subjects were statistically alike. A very good correlation was found between the frequencies recorded by this method and those reported in the literature and derived by various invasive physiological methods. The study of the distribution of energy contained in each derivation in a family of spectra permits determination of optimal electrode placement.

5034 FIBRINOGEN DEFICIENCY DURING THE COURSE OF TOXIC DIARRHEA. *(Pol.)* Kosinski, J.; Czarnecki, J. (W. Szenajch Munic. Child. Hosp., Torun, Poland). *Pediatr. Pol.* (2):239-240, 1975.

5035 GASTROINTESTINAL BLEEDING FROM A SURGICAL POINT OF VIEW. *(Ger.)* Heymann, H. (Ostadt Hosp., Hannover, Germany). *Med. Welt.* 25(36):1399-1404, 1974.

5036 GASTROINTESTINAL BLEEDING. *(Ger.)* Phlippen, R. (Med. Clin., Univ. Cologne, Germany). *Med. Welt.* 25(36):1394-1398, 1974.

5037 CHOLERA: REVIEW OF ITS ETIOLOGY, CLINICAL FEATURES, AND THERAPY. *(It.)* Rastelli, M. (Umberto I, Polyclin., Univ. Rome, Italy). *Clin. Eur.* 13(3):156-160, 1974.

5038 PREVENTION OF CHOLERA WITH DRUGS. *(It.)* Gaffi, A.; Businco, E.; De Pau, D. (Coll. Biol., Eur., Rome, Italy). *Clin. Eur.* 13(2):113-114, 1974.

5039 THE CLINICAL SIGNIFICANCE OF GASTROINTESTINAL HORMONES. *(Ger.)* Creutzfeldt, W. (Med. Clin., Univ. Gottinger, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:330-338, 1974.

5040 SOME PRINCIPLES FOR INTENSIVE TREATMENT OF CHOLERA AND CHOLERA-LIKE FORMS OF ACUTE INTESTINAL INFECTIONS. *(Rus.)* Bunin, K. V.; Sorinson, S. H. (I.M Sechenov Med. Inst., Moscow, USSR). *Klin. Med. (Mosk.)* 53(3):6-12, 1975.

5041 HYPEROXALURIA IN DISEASES OF THE GASTROINTESTINAL TRACT AND LIVER. *(Ger.)* Ruge, W.; Kohler, J.; Fromm, H.; Schindler, D.; Canzler, H. (Med. Coll., Hannover, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:533-535, 1974.

5042 CHOLEPERITONEUM AND BILE PERITONITIS. *(Sp.)* Vidal Sans, J.; Avila, F.; Gomez Conde, S.; Zanon, V.; Olsina, J. (Francisco Franco, Munic. Hosp. Barcelona, Spain). *Rev. Esp. Enferm. Apar. Dig.* 45(3):295-306, 1975.

5043 CRONKHITE-CANADA SYNDROME. *(Ger.)* Bartelheimer, W.; Lux, G.; Ottenjann, R.; Elster, K. (Neuperlach Munic. Hosp., Munich, Germany). *Z. Gastroenterol.* 12(8):609-610, 1974.

5044 THREE CASES OF SEVERE TYPHOID FEVER OBSERVED DURING THE TYPHOID FEVER EPIDEMIC IN KRASNIK FABRYCZNY. *(Pol.)* Mardarowicz, C.; Szyxzko, B.; Patorska-Mach, E.; Modrzewska, R. (Acad. Med., Lublin, Poland). *Przegl. Epidemiol.* 28(2):227-232, 1974.

5045 SECONDARY INTOLERANCE OF DISACCHARIDES DURING INFANTILE DIARRHEA. *(Pol.)* Maszewska-Kuzniarz, K.; Karczewska, K.; Dyduch, A. (Acad. Med.; Zabrze, Poland). *Pediatr. Pol.* 49(12):1479-1484, 1974.

5046 EPIDEMIOLOGIC ASPECTS OF TYPHOID FEVER IN A COUNTRY WITH A LOW INCIDENCE RATE. II. INCIDENCE AND ASYMPTOMATIC INFECTIONS: EFFECTIVENESS OF DETECTION OF ASYMPTOMATIC INFECTIONS. *(Pol.)* Pietkiewicz, K.; Buczowski, Z. (Nav. Med. Inst., Gdansk, Poland). *Przegl. Epidemiol.* 28(3):333-338, 1974.

5047 TREATMENT OF DIGESTION AND ABSORPTION DISTURBANCES IN CHILDREN WITH CHRONIC MALNUTRITION. *(Pol.)* Planeta-Malecka, I.; Kluska, J. (Acad. Med., Lodz, Poland). *Wiad. Lek.* 28(4):275-284, 1975.

5048 PRIMARY LYMPHORETICULAR NEOPLASMS OF DIGESTIVE TRACT. *(Pol.)* Sulocka, J.; Kobierska, A.; Krajewska, B. (Acad. Med., Gdansk, Poland). *Wiad. Lek.* 28(4):265-268, 1975.

5049 DISACCHARIDASE ACTIVITY IN SMALL INTESTINAL MUCOSA DURING INFANTILE ENTEROPATHY. *(Pol.)* Hager-Malecka, B.; Karczewska, K.; Dyduch, A. (no affil.). *Pediatr. Pol.* 49(12):1471-1477, 1974.

5050 LACTIC DEHYDROGENASE ACTIVITY AND PYRUVIC ACID LEVEL IN BLOOD IN ACUTE DIARRHEA IN INFANTS. *(Pol.)* Paczos-Chadyma, E. (Inst. Pediatr., Lublin, Poland). *Pediatr. Pol.* 49(6):669-678, 1974.

5051 HISTOCHEMISTRY OF HUMAN DUODENAL MUCOUS MEMBRANE. *(Cz.)* Kocianova, J.; Lojda, Z. (Bulovka Hosp., Prague, Czechoslovakia). *Vnitr. Lek.* 20(7):652-657, 1974.

5052 USE OF INTESTINAL PROBES FOR PREVENTION AND TREATMENT OF POSTOPERATIVE ABDOMINAL COMPLICATIONS. *(Rus.)* Shcherbakov, A. A. (Res. Lab. Proctol., Moscow, USSR). *Khirurgiia (Mosk.)* (12):91-96, 1974.

5053 MICROELEMENTS AND ELECTROLYTES IN THE SMALL INTESTINAL SECRETION OF PATIENTS WITH CHRONIC DIGESTIVE DISEASES. *(Rus.)* Revutsky, B. I.: Linevsky, Y. V. (Donetsk Med. Inst., USSR). *Vrach. Delo* 616(2):65-68, 1975.

5054 DECOMPRESSION GASTROSTOMY IN DIGESTIVE SURGERY: 100 CASES. *(Fr.)* Gignoux, M.; Bricard, H. (Surg. Clin. B, Univ. Caen, France). *Lyon Chir.* 71(1):58-60, 1975.

5055 THE ROLE OF THE LYMPH VESSEL SYSTEM IN DISEASES OF THE GASTROINTESTINAL TRACT. *(Ger.)* Meyer-Burg, J. (Steglitz Clin., Free Univ. Berlin, Germany). *Leber Magen Darm* 4(6):308-312, 1974.

5056 FUNCTIONAL ABDOMINAL COMPLAINTS: SYMPTOMS, BIOGRAPHY AND INTERRELATIONSHIPS. *(Ger.)* Schuffel, W. (Cent. Intern. Med. Pediatr., Univ. Ulm, Germany). *Leber Magen Darm* 4(3):66-103, 1974.

5057 PSYCHOSOMATIC PROBLEMS IN GASTROENTEROLOGY. *(Ger.)* Freyberger, H. (Univ. Hosp. Eppendorf, Hamburg, Germany). *Leber Magen Darm* 4(3):85-92, 1974.

5058 EFFECT OF CHEMOTHERAPY IN ACUTE SALMONELLOSIS ON THE DURATION OF FECAL SALMONELLA EXCRETION. A CATAMNESTIC STUDY IN THE CANTON OF ZUG (1969-1972). *(Ger.)* Hess, C. (Burgersp., Zug, Switzerland). *Schweiz. Rundschau Med.* 63(48):1430-1436, 1974.

5059 FUNCTIONAL RESULTS AFTER DUODENOPANCREATECTOMY (WITH SPECIAL CONSIDERATION OF IRON ABSORPTION, BREATH TEST, AND SERUM GASTRIN). *(Ger.)* Maurer, W.; Kaufmann, M.; Kaess, H.; Voirol, M.; Borel, G. A.; Deperrex, U.; Miller, G. (Burgersp., Solothurn, Germany). *Dtsch. Med. Wochenschr.* 99-(38):1863-1866, 1974.

5060 MEDICAL TREATMENT OF DIGESTIVE HEMORRHAGES. *(Sp.)* Kaufmann, P. (Fac. Med., Montevideo, Uruguay). *Cir. Urug.* 44(4):295-298, 1974.

5061 IATROGENIC DIGESTIVE HEMORRHAGES. *(Sp.)* Negrotto, J.; Niski de Rydel, R. (Fac. Med., Montevideo, Uruguay). *Cir. Urug.* 44(4):289-294, 1974.

5062 DIGESTIVE HEMORRHAGES: SURGICAL TREATMENT. *(Sp.)* Praderi, L. A. (Fac. Med., Montevideo, Uruguay). *Cir. Urug.* 44(4):299-305, 1974.

5063 SALIVARY GLAND CYLINDROMAS (ADENOID CYSTIC CARCINOMA). *(Fr.)* Baki, A.; Vaillant, J. M.; Brocheriou, C.; Laudenbach, P. (Salpetriere Hosp., Paris, France). *Bull. Cancer (Paris)* 61(4):501-508, 1974.

5064 TWO CASES OF TORSION OF THE GREATER OMENTUM. *(It.)* Balestrazzi, A. (Inst. Gen. Clin. Surg. Surg. Ther., Univ. Bari, Italy). *Chir. Gastroenterol.* 8(3):318-324, 1974.

5065 BIZARRE TUMORS (LEIOMYOBLASTOMA) OF DIGESTIVE TRACT SMOOTH MUSCULATURE. *(Sp.)* Diaz Watson, C.; Papamio Ruibal, A. (Cmdte. Manuel Fajardo Teaching Hosp., Havana, Cuba). *Rev. Cub. Cir.* 13(6):655-666, 1974.

5066 POLYPS IN THE UPPER GASTROINTESTINAL TRACT. *(Ger.)* Oltmanns, D.; Krautheim, J. (Acad. Med., Lubeck, Poland). *Med. Klin.* 69(43):1749-1755, 1974.

5067 INTESTINAL ABSORPTION OF VITAMIN D_3 AND CONVERSION INTO 25-OH D_3 DURING CHRONIC RENAL FAILURE. *(Fr.)* Bayard, F.; Bec, P.; Ton That, H.; Louvet, J. P.; Suc, J. M.; Boulard, C. (Fac. Med., Toulouse, France). *Rev. Med. Toulouse* 10(7):553-556, 1974.

5068 SURGERY AND PATHOLOGY OF THE BILE AND PANCREATIC DUCTS. *(Fr.)* Stalport, J. (no affil.). *Acta Gastroenterol. Belg.* 37(4/5):181-191, 1974.

5069 CLINICAL ASPECTS AND DIAGNOSIS OF OBSTRUCTIVE JAUNDICE IN TUMOR GROWTH. *(Rus.)* Shubin, B. M.; Rutoryan, E. S. (P. A. Gertsen Res. Inst. Oncol., Moscow, USSR). *Vopr. Onkol.* 21(2):40-44, 1975.

5070 THE CONGENITAL NATURE OF THE STENOSIS DUE TO THE DIAPHRAGMATIC COMPRESSION OF THE CELIAC ARTERY. A NEW ARGUMENT SUPPORTING THIS INTERPRETATION: THE CASES OF TWO SISTERS. *(Fr.)* Warter, J.; Storck, D.; Gillet, B.; Tongio. J. (Univ. Hosp. Cent., Strasbourg, France). *J. Med. Strasbourg* 5(5):369-375, 1974.

5071 INTESTINAL FORM OF CYTOMEGALY IN YOUNG CHILDREN. *(Rus.)* Pianov, R. P. (Gatchinsk Cent. Reg. Hosp., Leningrad Reg., USSR). *Vopr. Okhr. Materin. Det.* 18(12):25-29, 1974.

5072 SALMONELLA CARRIER STATE IN CHILDREN. *(Rus.)* Greshilo, M. S.; Silina, E. D. (N. I. Pirogov Med. Inst., Vinnitsa, USSR). *Vopr. Okhr. Materin, Det.* 18(12):21-24, 1974.

5073 DETERMINATION OF THE PHYSICOCHEMICAL NATURE OF SPECIFIC ANTIBODIES IN VARIOUS FORMS AND COURSES OF DYSENTERY IN CHILDREN. *(Rus.)* Nesterina, L. F.; Vasilieva, I. G. (Cent. Inst. Postgrad. Med., Moscow, USSR). *Vopr. Okhr. Materin. Det.* 18(12):16-20, 1973.

5074 STUDIES ON CHOLERA CRISIS-INHIBITING FACTORS: (2). PURIFICATION AND CHARACTERIZATION OF ACTIVE SUBSTANCES FROM SMALL INTESTINES OF IMMUNIZED RABBITS. *(Jpn.)* Morimoto, T.; Yamamoto, M.; Maruyama, S.; (Teikoka Hormone Mfg. Co. Ltd., Kawasaki, Japan). *J. Pharm. Soc. Jpn.* 94(12):1560-1565, 1974.

5075 PENETRATION OF Shigella INTO THE EPITHELEAL CELLS AS AN IMPORTANT CONDITION FOR THE DEVELOPMENT OF AN INFECTIOUS PROCESS. *(Rus.)* Petrovskaia, V. G. (Gamaleia Inst. Epidemiol. Microbiol., Moscow, USSR). *Zh. Mikrobiol. Epidemiol. Immunobiol.* 616(9):24-28, 1974.

5076 STUDY OF THE ETIOLOGICAL ROLE OF Klebsiella IN ACUTE INTESTINAL DISEASES. *(Rus.)* Samokhina, Z. F.; Gurevich, G. T.; Kuzina, M. F. (Minsk. Med. Inst., USSR). *Zh. Mikrobiol. Epidemiol. Immunobiol.* 616(8):64-67, 1974.

5077 LORAZEPAM IN THE MANAGEMENT OF GASTRO-INTESTINAL NEUROSES. *(E.)* El Roubi, A. (Dep. Med., Cairo Univ., Egypt). *J. Int. Med. Res.* 3(2):134-137, 1975.

5078 MARASMUS AND Pneumocystis carinii PNEUMONIA IN INSTITUTIONALISED INFANTS. OBSERVATIONS DURING AN ENDEMIC. *(E.)* Dutz, W.; Jennings-Khodadad, E.; Post, C.; Kohour, E.; Nazarian, I.; Esmaili, H. (Dep. Pathol., Univ. Pahlave, Shiraz, Iran). *Z. Kinderheilkd.* 117:241-258, 1974.

5079 THIORIDAZINE-INDUCED DIARRHOEA. *(E.)* Mitchell, A. B. S. (Charing Cross Hosp., London, England). *Postgrad. Med. J.* 51(593):182-183, 1975.

5080 NECROTIZING ENTERCOLITIS. *(E.)* Calahane, S. F.; Moore, B. (Child. Hosp., Dublin, Ireland). *Ir. J. Med. Sci.* 144(3):85-91, 1975.

5081 OCCULT GASTROINTESTINAL BLEEDING. AN EVALUATION OF AVAILABLE DIAGNOSTIC METHODS. *(E.)* Richardson, J. D.; McInnis, W. D.; Ramos, R.; Aust, J. B. (Univ. Texas Health Sci. Cent., San Antonio). *Arch. Surg.* 110(5):661-665, 1975.

5082 ENTEROPATHOGENIC Esch. coli GASTROENTERITIS IN PREMATURE INFANTS AND CHILDREN TREATED WITH FOSFOMYCIN. *(E.)* Baquero, F.; Canedo, T.; Rodriguez, A.; Jaso, E. (La Paz Pediatr. Clin., Auton. Univ. Madrid, Spain). *Arch. Dis. Child.* 50(5):367-372, 1975.

5083 REVERSIBLE FINGER CLUBBING IN A CASE OF PURGATIVE ABUSE. *(E.)* Silk, D. B. A.; Gibson, J. A.; Murray, C. R. H. (St. Bartholomew's Hosp., London, England). *Gastroenterology* 68(4):790-794, 1975.

5084 NEONATAL NECROTIZING ENTEROCOLITIS. EVOLUTION OF NEW PRINCIPLES IN MANAGEMENT. *(E.)* Wayne, E. R.; Burrington, J. D.; Hutter, J. (Child. Hosp., Denver, Colo.). *Arch Surg.* 110(5):476-480, 1975.

5085 CURRENT MANAGEMENT OF UPPER GASTROINTESTINAL BLEEDING. *(E.)* Yajko, R. D.; Norton, L. W.; Eiseman, B. (Denver Gen. Hosp., Colo.). *Ann. Surg.* 181(4):474-480, 1975.

5086 SURGICAL TREATMENT OF TYPHOID PERFORATION. *(E.)* Welch, T. P.; Martin, N. C. (Dep. Surg., Univ. Chiang Mai, Thailand). *Lancet* 1(7915):1078-1080, 1975.

5087 BIOCHEMICAL CHANGES IN SERUM FREE AMINO-ACIDS AND SERUM TRANSAMINASES IN INFANTILE GASTRO-ENTERITIS. *(E.)* Al-Nagdy, S. A.; Refai, F. M.; Khattab, A. K. (Dep. Biochem., Ein-Shams Univ, Cairo, Egypt). *Int. J. Biochem.* 5(3):251-256, 1974.

5088 THE USE OF A CARBOHYDRATE-FREE FEEDING FORMULA IN AUSTRALIAN ABORIGINAL CHILDREN WITH CHRONIC DIARRHOEA. *(E.)* Gracey, M.; Henderson, R. (Princess Margaret Child. Med. Res. Found., Perth, Australia). *Aust. Paediatr. J.* 10(3):164-167, 1974.

5089 DIETARY FIBRE AND 'PRESSURE DISEASES'. *(E.)* Burkitt, D. P. (Med. Res. Counc., London, England). *J. R. Coll. Physicians Lond.* 9(2):138-147, 1975.

5090 INTESTINAL DISACCHARIDASES IN HYPOPROTEINAEMIC STATES. *(E.)* Rastogi, M.; Misra, R. C.; Sarin, G. S.; Srivastava, P. N.; Chuttani, H. K. (Maulana Azad Med. Coll., New Delhi, India). *J. Assoc. Physicians India* 22(12):889-892, 1974.

5091 EFFECTS OF FRUCTOSE ON FERRIC AND FERROUS IRON ABSORPTION IN MAN. WITHIN-SUBJECT STUDY WITH THE ^{59}Fe-ABSORPTION WHOLE-BODY-RETENTION TEST IN SUBJECTS WITH NORMAL AND DEPLETED IRON STORES. *(E.)* Heinrich, H. C.; Gabbe, E. E.; Bruggemann, J.; Oppitz, K. H. (Univ. Hosp. Eppendorf, Hamburg, Germany). *Nutr. Metab.* 17(4):236-248, 1974.

5092 THE RELATIONSHIP OF THE FECES PROTEIN PARTICLES TO RICE PROTEIN BODIES. *(E.)* Tanaka, Y.; Hayashida, S.; Hongo, M. (Dep. Agric. Chem., Kyushu Univ., Fukuoka, Japan). *Agric. Biol. Chem.* 39(2):575-578, 1975.

5093 NATURAL HISTORY AND EXPERIENCE WITH DIAGNOSIS AND TREATMENT OF THE ZOLLINGER-ELLISON SYNDROME. *(E.)* Thompson, J. C.; Reeder, D. D.; Villar, H. V.; Fender, H. R. (Univ. Texas Med. Branch, Galveston). *Surg. Gynecol. Obstet.* 140(5):721-739, 1975.

5094 ALCOHOLISM AND THE RISK OF CANCER. *(E.)* Lowenfels, A. B. (New York Med. Coll., Valhalla). *Ann. NY Acad. Sci.* 252:366-373, 1975.

5095 MODEL FOR THE GROWTH OF A SOLID IN VITRO TUMOR. *(E.)* Deakin, A. S. (Dep. Applied Math., Univ. West. Ontario, Canada). *Growth* 39(1): 159-165, 1975.

5096 TOTAL HUMAN BODY PROTEIN SYNTHESIS IN RELATION TO PROTEIN REQUIREMENTS AT VARIOUS AGES. *(E.)* Young, V. R.; Steffee, W. P.; Pencharz, P. B.; Winterer, J. C.; Scrimshaw, N. S. (Dep. Nutr. Food Sci., Massachusetts Inst. Tech., Cambridge). *Nature* 253(5488):192-193, 1975.

5097 SULFATE-INDUCED DIARRHEA. *(Ger.)* Schmidt-Kessen, W.; Witte, O. (Inst. Balneol. Clim. Physiol., Univ. Freiburg/Breisgau, Germany). *Z. Gastroenterol.* 13(1):12-18, 1975.

5098 DEFICIENCY OF DISACCHARIDASES AND ALKALINE PHOSPHATASE IN SMALL INTESTINE MUCOSA IN PATIENTS WITH SOME ACUTE INTESTINAL INFECTIONS. *(Rus.)* Bobkova, S. D.; Shalygina, P. B.; Iushchuk, N. D. (Cent. Res. Inst. Epidemiol., Moscow, USSR). *Vopr. Med. khim.* 20(3):243-248, 1974.

5099 SECRETORY AND MORPHOLOGICAL DISORDERS OF THE STOMACH AND DUODENUM IN PATIENTS WITH CHRONIC HEPATITIS AND CIRRHOSIS OF THE LIVER. *(Rus.)* Iakhontova, O. I.; Krutskikh, E. V.; Valenkevich, L. N. (Leningrad Med. Inst. Sanit. Hyg., USSR). *Klin. Med. (Mosk.)* 52(7):67-72, 1974.

5100 QUANTITATIVE FUNCTIONAL EXPLORATION OF THE SALIVARY GLANDS. *(Fr.)* Ingrand, J.; Danchot, J.; Menkes, C. J.; Delbarre, F.; Roucayrol, J. C. (Cochin Hosp., Paris, France). *Nouv. Presse. Med.* 4(6):395-400, 1975.

5101 ACINIC CELL ADENOCARCINOMA OF THE MINOR SALIVARY GLANDS: A LIGHT MICROSCOPIC AND ULTRASTRUCTURAL STUDY OF A CASE. *(Jpn.)* Esaki, T.; Katoch, Y.; Yoshida, M.; Takeuchi, J. (Dep. Pathol., Aichi-Gakuin Univ., Nagoya, Japan). *Jpn. J. Cancer Clin.* 20(7):553-560, 1974.

5102 FUNCTIONAL MORPHOLOGY OF THE SMALL INTESTINE MUCOSA IN PATIENTS WITH CHOLERA. (FROM ASPIRATION BIOPSY FINDINGS). *(Rus.)* Shalygina, N. B. (Cent. Res. Inst. Epidemiol., Moscow, USSR). *Arkh. Patol.* 36(11):16-22, 1974.

5103 FINDINGS ON ASPIRATION BIOPSIES FROM THE INTESTINAL MUCOSA IN PHENYLKETONURIA. *(Ger.)* Cobet, G.; David, H.; Mucke, D.; Nitz, I.; Robbe, K. (Dep. Med., Humboldt Univ., Berlin, Germany). *Paediatr. Grenzgeb.* 13(1):13-22, 1974.

5104 GASTROINTESTINAL PERFORATIONS IN INFANCY. ANATOMIC AND ETIOLOGIC GAMUTS. *(E.)* Tucker, A. S.; Soine, L.; Izant, Jr., R. J. (Univ. Hosp., Cleveland, Ohio). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(4):755-763, 1975.

5105 TRANSMISSIBLE ENTEROCOLITIS IN HAMSTERS CAUSED BY TYZZER'S ORGANISM. *(E.)* Nakayama, M.; Saegusa, J.; Itoh, K.; Kiuchi, Y.; Tamura, T.; Ueda, K.; Fujiwara, K. (Inst. Med. Sci., Univ. Tokyo, Japan). *Jpn. J. Exp. Med.* 45(1):33-41, 1975.

5106 ON THE BIOCHEMICAL BASIS OF HEREDITARY FRUCTOSE INTOLERANCE. *(E.)* Koster, J. F.; Slee, R. G.; Fernandes, J. (Med. Fac., Erasmus Univ., Rotterdam, The Netherlands). *Biochem. Biophys. Res. Commun.* 64(1):289-294, 1975.

5107 TYPHOID γG, γM AND γA ANTIBODIES IN PERSONS WITH DIFFERENT RELATION TO THE TYPHOID INFECTION. *(E.)* Ciznar, I.; Farbakyova, G.; Draskovicova, M.; Karolcek, J. (Res. Inst. Epidemiol. Microbiol., Bratislava, Czechoslovakia). *Zentralbl. Bakteriol.* [*Orig. A*] 231(1-3):108-115, 1975.

5108 LOWERED SERUM CHOLESTEROL FOLLOWING THE INGESTION OF A HYDROPHILIC COLLOID. *(E.)* Lieberthal, M. M.; Martens, R. A. (Bridgeport Hosp., Conn.). *Am. J. Dig. Dis.* 20(5):469-474, 1975.

5109 VASCULAR TUMORS OF THE SALIVARY GLANDS IN CHILDREN. *(E.)* Hebert, G.; Ouimet-Oliva, D.; Ladouceur, J. (Notre Dame Hosp., Montreal, Canada). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(4):815-819, 1975.

5110 SURGICAL MANAGEMENT OF INFANTILE ULCERATIVE ENTERITIS. *(E.)* Miller, R. C.; (Univ. Mississippi Med. Cent., Jackson). *J. Pediatr. Surg.* 10(3):367-373, 1975.

5111 MANAGEMENT OF PAROTID GLAND TUMORS IN INFANTS AND CHILDREN. *(E.)* Chong, G. C.; Beahrs, O. H.; Chen, M. L. C.; Hayles, A. B. (Mayo Grad. Sch. Med., Univ. Minnesota, Rochester). *Mayo Clin. Proc.* 50(5):279-283, 1975.

5112 AN OUTBREAK OF GASTROENTERITIS DUE TO E. coli 142 IN A NEONATAL NURSERY. *(E.)* Boyer, K. M.; Petersen, N. J.; Farzaneh, I.; Pattison, C. P.; Hart, M. C.; Maynard, J. E. (U.S. Public Health Serv., Phoenix, Ariz.). *J. Pediatr.* 86(6): 919-927, 1975.

5113 TREATMENT OF ACRODERMATITIS ENTEROPATHICA WITH ZINC SULFATE. *(E.)* Robertson, A. F.; Sotos, J. (Med. Coll., Augusta, Ga.). *Pediatrics* 55(5):738-739, 1975.

5114 DIARRHOEA AND DIGESTIVE ENDOCRINE TUMOURS. *(E.)* Rambaud, J. C.; Matuchansky, C. (no affil.). *Clin. Gastroenterol.* 3(3):657-670, 1974.

5115 ZOLLINGER-ELLISON SYNDROME: NATURAL HISTORY AND DIAGNOSIS. *(E.)* Bonfils, S.; Bernades, P. (no affil.). *Clin. Gastroenterol.* 3(3): 539-557, 1974.

5116 MULTIPLE ENDOCRINE ADENOMATOSIS; MULTIPLE HORMONE-PRODUCING TUMOURS, A FAMILIAL SYNDROME. *(E.)* Wermer, P. (no affil.). *Clin. Gastroenterol.* 3(3):671-684, 1974.

5117 THE ENDOCRINE CELLS OF THE GI TRACT: ORIGENS, MORPHOLOGY AND FUNCTIONAL RELATIONSHIPS IN HEALTH AND DISEASE. *(E.)* Pearse, A. G. E. (no affil.). *Clin. Gastroenterol.* 3(3):491-510, 1974.

5118 PATHOLOGY OF ENDOCRINE TUMOURS OF THE GI TRACT. *(E.)* Martin, E. D.; Potet, F. (no affil.). *Clin. Gastroenterol.* 3(3):511-532, 1974.

5119 FATAL Yersinia enterocolitica SEPTICAEMIA. *(E.)* Josefsson, K.; Linberg, A. (Cent. Hosp., Halmstad, Sweden). *Scand. J. Infect. Dis.* 7(1):76-77, 1975.

5120 NATURAL HISTORY AND DIAGNOSIS OF THE CARCINOID SYNDROME. *(E.)* Grahame-Smith, D. G. (no affil.). *Clin. Gastroenterol.* 3(3):575-594, 1974.

5121 NON-B ISLET TUMOURS AND THE SYNDROME OF WATERY DIARRHOEA, HYPOKALAEMIA AND HYPOCHLORHYDRIA. *(E.)* Verner, J. V.; Morrison, A. B. (no affil.). *Clin. Gastroenterol.* 3(3):595-608, 1974.

5122 MODERN CONCEPTS IN THE MANAGEMENT OF GASTROJEJUNOCOLIC FISTULA. *(E.)* Hodgson, J.; Medina, O. F.; Teodorescu, M.; Messe, A. A. (Bronx VA Hosp., N.Y.). *Mt. Sinai J. Med. NY* 42(3): 239-244, 1975.

5123 HEREDITARY TELANGIECTASIA MANIFESTED AS GASTROINTESTINAL BLEEDING WITHOUT EXTERNAL VISIBLE TELANGIECTASIA. *(E.)* McCaffery, Jr., T. D.; Lilly, J. O. (Louisiana State Univ. Med. Cent., New Orleans). *Am. J. Gastroenterol.* 63(4): 327-332, 1975.

5124 SALIVARY GLAND DISEASE. *(E.)* Chisholm, D. M.; Mason, D. K. (Dep. Oral Med. Pathol., Univ. Glasgow, Scotland). *Br. Med. Bull.* 31(2):156-158, 1975.

5125 RECENT ADVANCES IN PHYSIOLOGY OF SALIVARY GLANDS. *(E.)* Garrett, J. R. (King's Coll. Hosp. Med. Sch., London, England). *Br. Med. Bull.* 31(2):152-155, 1975.

5126 THE INVESTIGATION OF ACUTE UPPER GASTROINTESTINAL HAEMORRHAGE. *(E.)* Forrest, J. A. H.; Finlayson, N. D. C. (R. Infirm., Edinburgh, Scotland). *Br. J. Hosp. Med.* 12(2):160-167, 1974.

5127 SEPTICAEMIA DUE TO Yersinia enterocolitica IN A NON-COMPROMISED HOST. *(E.)* Eriksson, M.; Olcen, P. (Reg. Hosp., Orebro, Sweden). *Scand. J. Infect. Dis.* 7(1):78-80, 1975.

5131 AMEBIC COLITIS MISTAKEN FOR INFLAMMATORY BOWEL DISEASE. *(E.)* Tucker, P. C.; Webster, P. D.; Kilpatrick, Z. M. (Med. Coll. Georgia, Augusta). *Arch. Intern. Med.* 135(5):681-685, 1975.

Ten cases of patients with amebic colitis which had been mistaken for inflammatory bowel disease was described. Similarities in clinical findings made diagnosis difficult; multiple stool examinations failed to demonstrate ova or trophozoites of *Entamoaba histolytica.* The indirect hemagglutination test was found to be a reliable diagnostic test in the evaluation of patients with inflammatory bowel disease. Substances taken early for symptomatic relief of diarrhea may interfere with the detection of amebas and lead to false-negative results; thus, amebiasis should be considered during the initial evaluation of patients with chronic diarrhea, especially if the diarrhea is bloody. The routine use of the serological test for amebiasis is recommended, followed by amebiasis treatment for all patients with colitis who have diagnostic indirect hemagglutination titers.

5132 BILHARIZIASIS: SIX CASES. *(Fr.)* St.-Yves, C.; Tremblay, M.; Garon, G.; Rousseau, B. (Hosp. Cent., Univ. Laval, Quebec, Canada). *Vie Med. Can. Fr.* 3(1):47-53, 1974.

Cases of bilharziasis caused by *Schistosoma mansoni* are reported. All six patients (five men, one woman, aged 21-58 yr) had just returned from a stay in Chad of 2 to 18 yr. Symptoms included asthenia, anorexia, nausea, vomiting, hyperthermia, abdominal cramps, diarrhea, bloody stool, icterus, and weight loss; two patients showed no symptoms at all. Examination of the urine showed no evidence of parasites in any of the cases, and examination of the stool showed only one egg in only one case. Rectal mucosal biopsy in five patients gave positive results; histological examination revealed tuberculoid granulomas in the submucosa, the larger of which contained eggs or egg fragments. The patient who did not undergo rectal mucosa biopsy had previously had a liver needle biopsy which proved the diagnosis of *S. mansoni* infection in addition to viral hepatitis. In all cases, there was peripheral eosinophilia, ranging from 730 - 1558 cells/ml. All patients were treated with niridazole, which produced side effects of headaches, myalgia, anorexia, nausea, vomiting, slowing of intestinal transit, and minor electrocardiogram changes. The absence of major side effects on the central nervous system is attributed to the mitigating effects of diazepam during treatment and the absence of portal hypertension at the time of treatment. The side effects were consistently more severe for the two patients with liver involvement. Eosinophilia increased during treatment, but gradually returned to normal several months after treatment.

159 IN VITRO STUDIES OF ULCERATIVE ILEOJEJUNITIS. *(E.)* Klaeveman, H. L.; Gebhard, R. .; Sessoms, C.; Strober, W. (Natl. Inst. Arthritis etab. Dig. Dis., Bethesda, Md.). *Gastroenterology* 8(3):572-582, 1975.

ehavior in organ culture and local immunoglobulin esponses were studied in tissue from a patient with chronic ulcerative ileojejunitis. The patient was a 42-yr-old Jewish male who presented with diarrhea and abdominal distention, digital clubbing and trace pedal edema. Small bowel x-rays showed an abnormal loop in the left upper quadrant with nodular indentations. Peroral jejunal biopsy showed complete villous atrophy with cuboidal pyknotic epithelial cells and a dense infiltrate of plasma cells, eosinophils and histiocytes. Intestinal biopsies were taken with the instrument placed fluoroscopically at the ligament of Treitz, rinsed in Krebs-Ringer bicarbonated buffer, cut into pieces 1-2 cm in diameter, and cultured in the presence and absence of gluten peptides. Specimens were also incubated in L-^{14}C-leucine for 90 min, the tissue homogenized, and the resulting homogenate incubated for 3 hr with anti-IgA antibodies linked to bromacetyl cellulose. Leucine incorporation into IgA after a 7 day gluten-containing diet was 32,647 counts/min/mg protein in comparison to 5830 counts/min/mg protein in eight normal individuals. Studies while the patient was on a gluten-free diet still showed an elevated count (34,000) but steroid therapy brought the values doen to 6814 after two months. Initial and 48 hr alkaline phosphatase values for organ cultured tissues were 51 and 262 μM *p*-nitrophenyl phosphate formed/g tissue/min, resp., after the gluten free diet and 108 and 497, resp., after the gluten-containing diet. In culture studies performed when the patient was on a gluten free diet, before the institution of corticosteroid therapy, initial alkaline phosphatase increased from 51 - 262 U. A similar increase to 242 U occured when gluten was present in the medium. It is concluded that chronic ulcerative ileojejunitis is a complication of gluten-sensitive enteropathy related to a non-gluten dependent pathological process involving the local immunological system.

5160 THE THYROID IN ULCERATIVE COLITIS AND CROHN'S DISEASE. IV. THYROID HORMONE BINDING PROTEINS.

(E.) Jarnerot, G.; Truelove, S. C.; von Schenck, H. (Radcliffe Infirm., Oxford, England). *Acta. Med. Scand.* 197(1/2):95-98, 1975.

The serum concentrations of the thyroid binding proteins were studied in patients with ulcerative colitis or Crohn's disease. Of the 20 patients studied, 11 had ulcerative colitis, of whom 8 had universal, and 3 distal involvement. Of the nine with Crohn's disease, 4 had colonic disease, three small bowel disease, and two ileocecal inflammation. Ten of the patients were on corticosteroid treatment (30-60 mg prednisolone/day). Controls were 20 healthy subjects not on any medication. Serum thyroxine binding globulin and thyroxine binding prealbumin were measured by agar gel electrophoresis and serum albumin was measured with bromcresol green. Serum thyroxine was determined by competitive protein binding, and thyroid stimulating hormone by radioimmunoassay. Thyroxine binding globulin levels were significantly higher in patients not taking corticosteroids than in controls (28.1 and 19.3 μg/100 ml, resp.), while thyroxine binding prealbumin levels were significantly lower (90.9 and 142.8 μg/100 ml, resp.). Thyroxine levels did not differ significantly, nor did triiodothyronine uptake. Patients receiving corticosteroids had significantly lower serum albumin levels than those not recieving them (32.3 and 40.3 μg/100 ml, resp.). The correlation between thyroxine binding prealbumin and albumin was significant when estimated for patients and controls as one group. Patients with no corticosteroid therapy had a significantly higher free thyroxine index than the controls (4.4 and 3.9 μg/100 ml, resp.). The thyroid stimulating hormone level was normal in all patients and controls. It is concluded that in ulcerative colitis and Crohn's disease changes can occur in serum concentrations of thyroxine binding proteins which may cause alterations in thyroid tests.

5161 THE THYROID IN ULCERATIVE COLITIS AND CROHN'S DISEASE. III. THE DAILY FRACTIONAL TURNOVER OF THYROXINE.

(E.) Jarnerot, G.; Truelove, S. C.; Warner, G. T. (Radcliffe Infirm., Oxford, England). *Acta. Med. Scand.* 197(1/2):89-94, 1975.

Patients with ulcerative colitis or Crohn's disease were studied with respect to alterations in thyroxine metabolism. There were five patients with ulcerative colitis, of whom four had universal and one had distal involvement; and six patients with Crohn's disease, of whom three had extensive colonic disease, two widespread small bowel disease, and one ileocecal inflammation. Six of the 11 were severely ill and seven were treated with corticosteroids. None had evidence of thyroid disease. Eight healthy patients, of whom none were on any medication, served as controls. The thyroid was blocked by 240 mg potassium iodide given p.o. in two doses over 24 hr, and the blockade maintained by 60 mg twice daily throughout the experiment. One day after the start of the blockade, blood was drawn for T_4 estimation, immediately followed by i.v. injection of 10 μCi ^{131}I-T_4 in normal saline. Readings were made with a whole body counter once daily for six to ten days, considering the value 24 hr after administration as 100%. A thyroid count was taken 24 hr after injection and compared with a similar control count from the thigh. The daily retained radioactivity plotted semi-logarithmically produced a straight line. The thyroid count 24 hr after injection showed no appreciable amounts of the dose had been taken up by the thyroid. The patients had a significantly shorter ^{131}I-T_4 biological half-life and a higher daily fractional turnover than the controls. Severely ill patients had more pronounced changes than the mildly or moderately ill, or the controls. Corticosteroid treatment did not change either the half-life or the daily fractional turnover. Extrathyroidal T_4 iodine pools were not significantly smaller for the patients as a group than for the controls. Plasma T_4 and total T_4 iodine disposed/day did not differ significantly between patients and controls. It is concluded that patients with severe Crohn's disease or ulcerative colitis have increased daily fractional turnover of T_4.

5162 A STUDY OF THE CELLULAR INFILTRATE OF THE PROXIMAL JEJUNAL MUCOSA IN ULCERATIVE COLITIS AND CROHN'S DISEASE.

(E.) Ferguson, R.; Allan, R. N.; Cooke, W. T. (Gen. Hosp., Birmingham, England). *Gut* 16(3):205-208, 1975.

The inflammatory cell infiltrate was studied from proximal jejunal biopsies of patients with ulcerative colitis, and patients with Crohn's disease. Of 20 ulcerative colitis patients, seven had active disease, six were on steroid therapy, eight had total colonic involvement, five had distal colonic involvement, and seven had undergone panproctocolectomy. Of 26 patients with Crohn's disease, 16 had active disease, six were on steroids, four had known jejunal involvement, six had terminal ileal and colonic involvement, three colonic involvement only and four had ileal involvement only. For controls, 20 obese patients undergoing jejunoileal bypass were used. Biopsy specimens were taken from the first 10 cm of jejunum. Sections 5 μ thick were made and stained with hematoxylin and eosin. Cell counts were made in at least three areas of each section and the number of cells/mm^2 of lamina propria and cells/mm length of epithelium calculated. Plasma cells, lymphocytes, eosinophils, neutrophils, reticulum cells, or other cells in the lamina propria were counted. There were no differences in the lymphocyte counts in either tissue between any of the groups. However, patients with ulcerative colitis had higher lamina propria plasma cell counts (2268) than controls (1050) and Crohn's disease patients had higher counts (3002) than the ulcerative colitis patients. There were no significant differences between those with active or inactive disease, or those on steroid therapy and those not. In the ulcerative colitis patients, there were no significant differences between those with total colonic involvement and those with distal involvement, nor between all these patients and those who had previously undergone panproctocolectomy. In patients with Crohn's disease there were no differences between the various types of involvement. In this disease, the plasma cells outnumbered the lymphocytes in 15 biopsies. This was seen in only four ulcerative colitis patients, three of whom had active disease. It is concluded that raised plasma cell counts are present in ulcerative colitis and Crohn's disease, and may indicate an abnormal antigen in the proximal intestine.

5163 STRICTURE OF THE ANORECTUM IN CROHN'S DISEASE INVOLVING THE COLON. *(E.)* Greenstein, A. J.; Sachar, D. B.; Kark, A. E. (Mount Sinai Hosp., City Univ. New York, N.Y.). *Ann. Surg.* 181(2):207-212, 1975.

Twelve patients with anorectal stricture in a series of 160 patients with non-specific colitis (excluding ulcerative colitis) were studied. Of the 12, four had granulomatous colitis and eight had ileocolitis. Their ages ranged from 10-79 yr at the time of stricture development, but the mean duration from onset to the development of significant stricture was 14 yr. Nine of the 12 patients had strictures beginning 1/2 to 4 cm from the anal verge, three of which were short, fibrous, and diaphragmatic. The remaining five extended into the rectum for varying distances. Three of the 12 had strictures beginning 4, 5, and 7 cm from the anal verge and were either annular (under 2 cm) or tubular (over 2 cm), one of them extending to the rectosigmoid junction. Incontinence was found in three of the 12. Other pertinent clinical features were perianal disease (in 10), associated fibrous stricture or radiological narrowing (in 10) and discontinuity of the disease. Associated internal fistulae occurred in five and shortening of the bowel in three patients. Six had noncaseating granulomas. It is concluded that anorectal stricture occuring in Crohn's disease presents a major clinical problem, may lead to partial or complete obstruction, and may be associated with perianal disease, multiple fistulae, proximal stricturing in the bowel, and activity of Crohn's disease elsewhere.

5164 CHANGES IN THE BIDIRECTIONAL SODIUM FLUX ACROSS THE INTESTINAL MUCOSA IN CROHN'S DISEASE. *(E.)* Allan, R.; Steinberg, D. M.; Dixon, K.; Cooke, W. T. (Gen. Hosp., Birmingham, England). *Gut* 16(3):201-204, 1975.

Bidirectional sodium flux and net sodium absorption were compared in 10 patients with Crohn's disease and 11 patients with ulcerative colitis. All patients had been given a panproctocolectomy and ileostomy 1-15 yr previously, and were in good health with no radiological abnormality. After a 4 hr fast the patients were fitted with a nasogastric tube and a temporary ileostomy bag connected to a volume meter. Hartmann's solution (sodium 154 mEq/liter) was infused through the tube at 33 ml/min for 1 hr after an ileostomy output of 20-40 ml/min was established. Then 4 μCi ^{22}Na in 20 ml Hartmann's solution and 5 ml 1% BSP solution were given in a bolus *via* the tube, and the normal infusion of Hartmann's solution was continued for a second hr. The ileostomy output was measured by liquied scintillation counter in four 15 min aliquots and a fifth sample taken after the second hr. The last sample represented the concentration of label absorbed and resecreted from plasma to lumen, and was subtracted from the label absorbed and resecreted from plasma to lumen, which was subtracted from the label in the first four aliquots to give the fraction absorbed. The mean ileostomy output was significantly greater in the Crohn's disease patients than those with ulcerative colitis during the first hr but not during the second. The mean sodium flux both from lumen to plasma and from plasma to lumen was significantly lower in the Crohn's disease patients (3.30 and 2.30 mEq sodium/min, resp.) than in the ulcerative colitis patients (6.15 and 4.81 mEq sodium/min, resp.). There was no significant difference in the net absorption of sodium in the two groups. It is concluded that in Crohn's disease the gut may be more extensively involved than is shown by radiological appearance.

5165 THE THYROID IN ULCERATIVE COLITIS AND CROHN'S DISEASE. I. THYROID RADIOIODIDE UPTAKE AND URINARY IODINE EXCRETION. *(E.)* Jarnerot, G. (Med. Sch., Linkoping Univ., Sweden). *Acta Med. Scand.* 197(1/2):77-81, 1975.

Two studies were conducted to compare the prevalence of iodine depletion in chronic inflammatory bowel disease patients and healthy controls. The first study involved 50 patients, 10 of whom had distal and 10 universal ulcerative colitis; and 28 had Crohn's disease, of whom four had anorectal lesions, 11 more widespread colonic lesions, and 13 small bowel lesions. Two patients had unclassified colitis. During the study 15 patients were given corticosteroids, and 32 Salazopyrin. All had 24 hr urine samples collected and analyzed for iodine excretion. Forty of the patients, of whom 15 were on a milk free diet, answered a dietary questionnaire, and were compared to 102 normal controls. The second study involved 38 patients of whom five had distal and nine universal ulcerative colitis, and 23 had Crohn's disease, of whom three had anorectal lesions, nine widespread colonic lesions, and 11 small bowel lesions. Thirty five were also included in the first study. Thirteen were given corticosteroids and 24 salicyclazosulfapyridine. Of the 35 patients in both studies, 12 were on corticosteroids. All second study patients had thyroid radioiodide uptake measured 24 hr after an oral test dose of 10 μCi ^{131}I. Of the 38 patients who answered a dietary questionnaire, 10 were on a milk-free diet. All were compared with a group of 36 healthy controls. The patient groups had considerably lower urinary iodine excretion levels and higher thyroid ^{131}I uptake levels than the corresponding control groups. All differences were significant except for radioiodide uptake in the males. Iodine excretion was significantly higher in the males than the females in both patient and control groups. Of the 50 patients in the first study, 10 had a 24 urinary iodine excretion of less than 40 μg, while five of the 102 controls did, a significant difference. Of 50 patients, 26 excreted less than 70 μg, compared to 28 of the 102 controls, a highly significant difference. Of the 38 patients in the second study, 16 had a 24-hr radioiodide uptake of 50% or more, while only four of the 36 controls had as great an uptake, a significant difference. Neither corticosteroid, salicylazosulfapyridine, nor milk-free diet had any effect on iodine excretion or iodide uptake. Patients not treated with corticosteroids, however, showed a highly significant negative correlation between excretion and uptake. There was no relation between excretion or uptake and the site of bowel disease. It is concluded that patients with chronic inflammatory bowel disease have increased thyroid uptake and diminished urinary iodine excretion, indicating iodine depletion.

5166 THE DISTRIBUTION OF MUCOSAL ANTIBODIES IN THE BOWEL OF PATIENTS WITH CROHN'S DISEASE.

(E.) Green, F. H. Y.; Fox, H. (Dep. Pathol., Univ. Manchester, England). *Gut* 16(2):125-131, 1975.

The relative amounts of immunoglobulin-containing cells were studied in the affected gut areas of patients with Crohn's disease. Surgically resected unfixed specimens of large and small intestine were obtained from 24 patients. Blocks were taken from the resection lines, ulcerated areas, affected areas without ulceration, unaffected areas, and, when possible, attached mesenteric lymph nodes. Control blocks were taken from both large and small intestine from patients with carcinoma of the colon, and from normal peroral jejunal biopsies. The sections were fixed in acetone and stained directly or indirectly with anti-human IgA, IgM, IgG, antisera conjugated with fluorescein and isothiocyanate, and IgE antisera conjugated with fluorescein only. For controls, unstained sections were used to estimate autofluorescence. The identity of specifically fluorescent cells was checked by photographing them and restaining them with hematoxylin and eosin. In the Crohn's disease, the unaffected areas showed a slight increase in the IgA-containing cells of the lamina propria, while the epithelial IgA distribution was similar to that of controls. There was a definite increase in number of IgM-containing cells, to amounts equalling that of the IgA-containing cells, the epithelial fluorescence of the two showing a similar pattern in 19 papers. Distribution of IgG, IgD, and IgE-containing cells was similar to that of controls. Sections from abnormal but non-ulcerated areas showed a marked decrease in lamina propria IgA-containing cells. Intraepithelial IgA was reduced proportionately. IgM cell number was reduced relative to the unaffected areas but not to the controls. Epithelial IgM was largely absent. Cells containing other immunoglobulins did not differ significantly from controls or unaffected areas. In the ulcerated sections the inflammatory infiltrate contained moderate numbers of IgA, IgM, and IgG-containing cells in descending order. Lymphoid follicles containing predominantly IgA-containing cells were common in the submucosa, subserosa, and lymph nodes. The controls contained a predominance of IgA-containing cells in the plasma cells, and IgA in the epithelial cells. No epithelial fluorescence was seen when stained for other immunoglobulins. It is concluded that there is a focal reduction in IgA in the lamina propria and epithelium, confined to histologically abnormal areas in Crohn's disease, especially where the mucosa is still intact.

5167 FAT-REDUCED DIET IN THE SYMPTOMATIC TREATMENT OF PATIENTS WITH ILEOPATHY: A FOLLOW-UP STUDY.

(E.) Andersson, H. (Sahlgrenska Hosp., Univ. Goteborg, Sweden). *Nutr. Metab.* 17(2):102-111, 1974.

Of 13 patients with chronic diarrhea who favorably responded to a low-fat diet in a previous clinical study, 10 were followed up for 3-27 months while continuing the diet. Of the 10, 9 had Crohn's disease and 7 of these had had an ileal resection. The 10th patient had had an extensive small bowel resection following a car accident. After the completion of the initial clinical study, the patients were given individually worked out diets adapted for use at home and work, containing about 40 g fat/day. All patients were given vitamin supplements, and one took cholestyramine during the study. Most patients were interviewed and given blood tests and routine examinations every 34 months. Daily intake of energy and nutrients was determined and bowel habits were registered. After the course of study the patients were readmitted to the clinic and given the same standard low-fat diet they were given in the initial clinical study. Nitrogen, potassium and sodium in feces, urinary calcium excretion, and total body potassium were determined. Most patients had few or no difficulties in following the diet. Mean decrease in energy intake between the periods before and after treatment was about 600 kcal/day. Fat intake was reduced from about 155 g to about 50 g/day. Protein intake was not affected except for an appreciable increase in 2 patients. Bowel evacuations were reduced from 10-30/day before treatment to no more than 3/day after treatment, with 1 exception. In spite of the decreased caloric intake, body weight did not change significantly during the study. Total body potassium increased significantly in 5 patients. All patients showed low serum albumin, 2 abnormally so. In the clinic, following the at-home study, the daily number of stools and fecal excretion of fat, water, sodium, and nitrogen were all similar to values during the initial clinical period and the study period. It is concluded that a low-fat diet is beneficial in chronic diarrhea from ileal disease, even outside the hospital for a protracted period of time.

5168 CROHN'S DISEASE OF THE STOMACH: THE "RAM'S HORN" SIGN. *(E.)* Farman, J.; Faegenburg, D.; Dallemand, S.; Chen, C. K. (Downstate Med. Cent., Brooklyn, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):242-251, 1975.

The radiological appearance of the stomach in 12 patients (9 men and 3 women; average age 30 yr) with Crohn's disease was studied. All had small bowel disease of varying extent and severity. Duodenal involvement was present in 5, colonic in 4, and esophageal in 1. In 9 of the 12, involvement of the antrum of the stomach produced a tubular shape with conical narrowing: the "ram's horn" configuration. In these cases the stomach distended poorly and peristalsis was sluggish and infrequent. In 2 other patients there was a pyloroduodenal deformity and in 1, irregular, abnormal coarse antral mucosal disease. Gastric dilation resulting from pyloroduodenal stenosis was present in 2 cases and excess retained gastric secretion in 3. The gastric mucosa ranged in appearance from coarsened and pebbly to smooth. It is concluded that gastric Crohn's disease can be diagnosed radiologically by the presence of a smooth tubular, poorly distensible antrum with sluggish peristalsis; cobblestone antral folds, moderate pyloroduodenal outlet obstruction, excess gastric secretions, and presence of Crohn's disease elsewhere in the gastrointestinal tract.

5169 REGIONAL ENTERITIS OF THE DUODENUM. *(E.)* Thompson, W. M.; Cockrill, H. Jr.; Rice, R. P. (Duke Univ. Med. Cent., Durham, N. C.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(2):252-261, 1975.

The characteristic roentgen features of duodenal regional enteritis were reviewed in 23 patients. Of the 23, 16 underwent surgery and presented with histological evidence of Crohn's disease. Diagnosis of Crohn's disease was also made by roentgenograms of the upper and lower gastrointestinal tract in each case. Clinically, 22 of the patients had abdominal pain and diarrhea, and 16 had vomiting and postprandial fullness. Seven were anemic and 16 had significant weight loss. In 6 patients the initial clinical diagnosis was peptic ulcer disease. Seven who showed duodenal changes had no upper gastrointestinal symptoms other than occasional pain. Roentgenographically, the appearance of the patients was similar to those with regional enteritis of the small intestine. There was concurrent gastric involvement in seven cases. The early stages of the disease showed a more subtle and less specific involvement than advanced regional enteritis. Findings included blunted, thickened, and possibly disorganized mucosa, and moderate narrowing of the lumen with some spasm. The most characteristic change in the late stages of the disease was the pseudopost Billroth I sign, in which the antrum, pylorus, and duodenal bulb are blended into a single tubular structure. Other late changes included loss of normal mucosal pattern and appearance of pseudodiverticula with ulceration, and occasionally a nodular appearance of the mucosa; a smooth, tapered stenosis sometimes resulting in obstruction, and sometimes involving the apex of the duodenal bulb; and duodenal fistulae, usually from the transverse colon to the second portion of the duodenum. It is concluded that Crohn's disease of the duodenum is more common than previously thought, and tubular narrowing of the antrum, pylorus, duodenal bulb, and second portion of the duodenum is diagnostic of the condition.

5170 TRANSPLANTATION ANTIGENS IN CROHN'S DISEASE: LINKAGE OF ASSOCIATED ANKYLOSING SPONDYLITIS WITH HL-AW 27. *(E.)* Russell, A. S.; Percy, J. S.; Schlaut, J.; Sartor, V. E.; Goodhart, J. M.; Sherbaniuk, R. W.; Kidd, E. G. (Dep. Med., Univ. Alberta, Edmonton, Canada). *Am. J. Dig. Dis.* 20(4):359-361, 1975.

The HL-A antigen profile was studied in 77 patients with Crohn's disease to determine if any significant linkage exists between a genetic susceptibility to this disease and any of the transplantation antigens. A microcytotoxicity technique was used to determine the complete HL-A antigen profile in the Crohn's disease patients, 11 of whom had ankylosing spondylitis, and 600 controls. The profiles did not differ significantly between patients and controls. However, among the 11 males with ankylosing spondylitis, 10 patients were positive for HL-Aw 27; the frequency of this antigen in this series resembled that found in spontaneous ankylosing spondylitis. Among the other 66 Crohn's disease patients, three females had HL-Aw 27 with no evidence of sacroiliitis. In seven patients with Crohn's disease and associated spondylitis, the spondylitis preceded Crohn's disease by 1.5-10 yr, while in two patients the diseases appeared at approximately the same time and in two others Crohn's disease preceeded the spondylitis by 0.5-3 yr. The results suggest that the HL-Aw 27 antigen may be a useful indicator of spondylitis in Crohn's disease.

5171 CLINICAL PATTERNS IN CROHN'S DISEASE: A STATISTICAL STUDY OF 615 CASES. *(E.)* Farmer, R. G.; Hawk, W. A.; Turnbull, Jr., R. B. (Cleveland Clin. Found., Ohio). *Gastroenterology* 68(4):627-635, 1975.

Clinical patterns were studied in 615 cases of Crohn's disease to determine whether initial anatomic involvement in this disease is directly related to the clinical course and prognosis. The patients represented 615 consecutive cases of Crohn's disease seen between 1966 and 1969. All data concerning these patients were subjected to statistical analysis based on determinations of anatomic involvement, clinical symptoms, course of the illness as shown by follow-up data, and surgical experience. The following initial clinical patterns were established: ileocolic pattern with involvement of the distal ileum and right colon (252 patients); small intestinal pattern with involvement of the small intestine but not the colon (176); colon pattern with colonic but not small intestinal involvement (114); and anorectal pattern with anorectal but not proximal colonic or small intestinal involvement (21). Statistically significant symptoms included rectal bleeding with colon involvement, and rectal fistulas with ileocolic or colon involvement. The statistically significant complications included: perianal fistulas, internal fistulas, and intestinal obstruction with the ileocolic pattern; perianal fistulas, toxic megacolon, and arthritis with the colon pattern; and intestinal obstruction with the small intestinal pattern. Surgery was required in 73% of the ileocolic pattern patients and 51% of the small intestinal and colon pattern patients. Anorectal involvement was rarely the initial manifestation, but frequently accompanied the ileocolic and colon patterns. There were postoperative recurrences in 27% of the patients with the ileocolic pattern, 21% of those with the small intestinal pattern, and 16% of those with the colon pattern. Death occurred in 7% of the ileocolic pattern patients, 5% of those with the colon pattern, and 4% of those with the small intestinal pattern. The data indicate that Crohn's disease should be considered as a protean disease with certain definable patterns and that anatomic involvement at the time of diagnosis bears directly on the clinical course, type of complications, and prognosis.

5172 REMEDIABLE DEFECTS IN CROHN DISEASE. A PROSPECTIVE STUDY OF 63 PATIENTS. *(E.)*

Beeken, W. L. (Dep. Med., Univ. Vermont, Burlington). *Arch. Intern. Med.* 135(5):686-690, 1975.

To identify potentially remediable abnormalities in Crohn's disease, the incidence of anemia, serum electrolyte deficiencies, defects in carbohydrate, fat, and vitamin B_{12} absorption, jejunal bacterial overgrowth, and abnormalities in intestinal protein metabolism were prospectively analyzed in 63 patients with this disorder. Radiological studies showed disease in the upper part of the small bowel in 14% of the patients, the mid-small bowel in 22%, the lower part of the small bowel in 76%, and the colon in 33%. Hematocrit values were less than 40 volume percent in 67% of the patients, and iron deficiency was found in 35%. In addition, 10 patients had low serum folate values and conventional Schilling tests with intrinsic factor were abnormal in 31 patients. Of the entire group, 44 patients had one or more potentially correctable causes of anemia; 21 had serum electrolyte abnormalities, the most common of which was hypocalcemia; 13 had abnormal lactose tolerance tests, and jejunal disease or bacterial overgrowth were possible contributing factors in six. Xylose malabsorption did not accurately reflect jejunal disease. All patients showed normal hydration and renal function. Of the 61 patients who completed fat balance testing, 19 had steatorrhea caused by a variety of factors. Derangements of protein metabolism were the most commonly encountered abnormalities: excessive enteric protein loss was present in 76%; fasting serum tryptophan values were low in 29 or 35 patients tested; fecal nitrogen and nitrogen balances were abnormal in most cases; and hypoalbuminemia was present in 16 patients. High bacterial colony counts were found in 30% of the jejunal cultures. In addition to the initial barium studies, Crohn's disease patients should be evaluated with regard to body weight, stool frequency, and anemia. A selective search for correctable abnormalities will often identify defects amenable to correction by appropriate replacement therapy.

5173 PRESTENOTIC ENTERITIS AND ENTEROCOLITIS IN CHILDREN: DESCRIPTION OF A SYNDROME AND REVIEW OF FIVE CASES. *(E.)*

Smith, E. I.; Gill, C. C. (Child. Mem. Hosp., Univ. Oklahoma Coll. Med., Oklahoma City). *South. Med. J.* 68(4): 427-430, 1975.

Case reports of five children with enteritis proximal to a stenotic area of the bowel are presented. The first patient was born with multiple congenital anomalies including a first arch syndrome and a low imperforate anus with a perineal fistula; she had perineal anoplasty on the seventh day of life. The second patient was a microcephalic male born with an imperforate anus; he had abdominoerineal anoplasty on the second day of life. The third patient (female) was born with multiple congenital anomalies including a high imperforate anus and had a colostomy performed soon after birth. The fourth case was a female born with a caudal duplication abnormality and anal atresia; she was subjected to numerous surgical procedures including a transverse colostomy as a neonate. The last case was a boy born with multiple atretic areas of the small intestine; intestinal obstruction was diagnosed at 72 hr of age. A clinical syndrome involving prestenotic enteritis and enterocolitis consisting of abdominal distention and pain, intermittent diarrhea and constipation, failure to thrive, fever, and, in some patients, extreme prostration and death was observed. The pathogenesis of this enteritis and enterocolitis was apparently related to partial mechanical obstruction of the bowel with proximal dilatation, stagnation, and capillary stasis. Acute relief from the enteritis and enterocolitis was obtained by stomal dilatation and colonic irrigation, but all patients eventually required surgical intervention. Because mortality in this disease is significant and the results of early surgical intervention are favorable, surgical intervention is encouraged at the first sign of prestenotic enteritis or enterocolitis in children. Surgical correction of the distal stenosis produced a growth spurt in the two successfully treated patients in this series without other growth-limiting diseases.

174 DIAGNOSIS OF CROHN'S RECURRENCE AFTER SUR-
GERY. *(E.)* Calvadetscher, P.; Deyhle, P.
Dep. Intern. Med. Univ. Zurich, Switzerland). *En-*
oscopy 7(1):27-29, 1975.

oloscopy was compared with clinical observation and
adiology in diagnosis of recurrent Crohn's disease
t or near the site of earlier surgery. Studies
ere done on 12 patients; the average interval be-
ween radiological and endoscopic examination was
3 days; the longest interval was 67 days. Recur-
ence was defined clinically as return of symptoms
fter a postoperative symptomless period; radio-
ogically as appearance of spiculas, cobblestone-
attern and restriction of the lumen; and endo-
copically as ulcerations and cobblestone pattern.
ndoscopy showed recurrence in 11 patients, while
adiology showed recurrence in only 3. An ulcer at
he anastomosis was shown in one case by radiology,
n contrast to 6 cases by endoscopy. Cobblestone
atterns were found by radiology in 3 of 5 patients.
hey produced clinical symptoms in 4. Clinical
ymptoms developed in 3 cases of anastomotic ulcers,
ndetected radiologically. It is concluded that en-
oscopy is superior to radiology in diagnosis of
hese recurrences, and can detect recurrences during
ymptomless phases.
